## Foreword

> "The number system is like human life. First you have the natural numbers. The ones that are whole and positive. Like the numbers of a small child. But human consciousness expands. The child discovers longing. Do you know the mathematical expression for longing? The negative numbers. The formalization of the feeling that you're missing something. Then the child discovers the in-between spaces, between stones, between people, between numbers and that produces fractions, but it's like a kind of madness, because it does not even stop there, it never stops... Mathematics is a vast open landscape. You head towards the horizon and it's always receding..."
> -Smilla Qaavigaaq Jaspersen, in the novel Smilla's Sense of Snow, by Peter Høeg (see [21]).

This book arose out of one of the more enjoyable undergraduate courses I taught at Drexel University: Mathematical Software. I taught it for many years without using a textbook (and probably never taught the same exact course twice!). I toyed with writing a text for it but never found the time.

The courses I taught are varying subsets of the material in this manuscript.

At Drexel, we used commercial software that had a very slick userinterface (and that gives incorrect results in an important case!). In this book, I use the free and open-source Maxima system with its wxMaxima interface.

Sections marked in this manner are more advanced or specialized and may be skipped on a first reading.
(2) Sections marked in this manner are even more advanced or specialized and may be skipped on a first reading (or skipped entirely).

I am grateful to the many editors of Wikipedia. The biographical sketches in this book owe a great deal to their vital work.

I am also grateful to Matthias Ettrich and the many other developers of the software, $\mathrm{L}_{Y} X$ - a free front end to $\mathrm{IAT}_{E} X$ that has the ease of use of a word processor, with spell-checking, an excellent equation editor, and a thesaurus. I have used this software for years and the current version is more polished and bug-free than most commercial software.

## Contents

Foreword ..... vii
List of Figures ..... xiii
Chapter 1. Introduction ..... 1
1.1. Installation and first steps ..... 1
Chapter 2. Number theory ..... 9
2.1. Introduction ..... 9
2.2. Euler's totient function ..... 14
2.3. Public-key cryptography ..... 15
2.4. Diffie-Hellman-Merkle key exchange ..... 19
2.5. Continued fractions ..... 21
Chapter 3. Basic algebra and calculus ..... 25
3.1. Functions and programming ..... 28
3.2. Limits ..... 36
3.3. Elimination theory ..... 37
Chapter 4. Differential Equations ..... 41
4.1. Introduction ..... 41
4.2. Into the wild ..... 50
4.3. The Heat Equation ..... 52
4.4. Solution to the Heat Equation ..... 59
4.5. Finer points of plotting ..... 61
4.6. The Wave Equation ..... 65
Chapter 5. Integral transforms ..... 75
5.1. The Fourier Transform ..... 75
5.2. The discrete Fourier transform ..... 77
5.3. The Laplace Transform ..... 80
Chapter 6. Orthogonal polynomials ..... 87
6.1. Introduction ..... 87
6.2. Weighted orthogonality ..... 91
Chapter 7. Linear Algebra ..... 99
7.1. Introduction ..... 99
7.2. Changes of basis ..... 107
7.3. Dot-products and projections ..... 109
7.4. Eigenvalues and the characteristic polynomial ..... 116
7.5. Functions of matrices ..... 129
7.6. Linear Programming ..... 132
Chapter 8. Calculus of Finite Differences ..... 143
8.1. A discrete introduction to finite differences ..... 143
8.2. Functional Programming and Macros ..... 148
Chapter 9. Nonlinear algebra ..... 153
9.1. Introduction ..... 153
9.2. Ideals and systems of equations ..... 153
9.3. Gröbner bases ..... 157
9.4. Buchberger's Algorithm ..... 158
9.5. Consistency of algebraic equations ..... 160
Chapter 10. Robot motion-planning ..... 163
10.1. A simple robot-arm ..... 163
10.2. A more complex robot-arm ..... 166
Chapter 11. Differential Game Theory, a Drive-by ..... 173
11.1. Dances with Limousines ..... 173
11.2. Rock, Paper, Rocket ..... 181
Chapter 12. Special Functions ..... 189
12.1. The Gamma Function ..... 189
12.2. Elliptic integrals and elliptic functions ..... 192
12.3. Bessel functions ..... 198
12.4. Airy functions ..... 201
12.5. Logarithmic and exponential integrals ..... 202
12.6. Lambert functions ..... 207
Chapter 13. The Zeta function ..... 211
13.1. Properties of the $\zeta$-function ..... 211
13.2. A "formula" for prime numbers ..... 218
Appendix A. Gröbner basis for the robotic motion problem ..... 225
Appendix B. Predefined values. ..... 231
Appendix C. Functional equation ..... 233
C.1. Poisson summation ..... 233
C.2. The main result ..... 234
Appendix D. Fermat factorization ..... 235
D.1. The algorithm ..... 235
D.2. Derivation of the upper bound for the number of iterations ..... 237
Appendix E. The Maxima Programming language ..... 239
E.1. Introduction ..... 239
E.2. Commands for functions and equations ..... 239
E.3. Trigonometric functions ..... 240
E.4. Logical Operations ..... 240
E.5. Looping constructs ..... 240
E.6. Lists ..... 241
E.7. Macros ..... 245
E.8. Input and Output ..... 247
Appendix F. Visual outputs ..... 251
F.1. Plotting ..... 251
F.2. plot3d ..... 257
F.3. Standalone commands ..... 261
F.4. Plot-outputs ..... 261
F.5. The draw commands ..... 262
Appendix. Solutions to Selected Exercises ..... 271
Appendix. Index ..... 287
Appendix. Bibliography ..... 293

## List of Figures

1.1.1 The complex plane ..... 5
3.0.1 Roots of a cubic equation ..... 26
3.1.1 Simple plot ..... 29
3.1.2 Lambda plots ..... 30
3.1.3 the block command ..... 32
3.1.4 Local variables in a block-command ..... 33
3.1.5 $f(x)$ written using a block-command ..... 33
3.1.6 False plot of $f(x)$ ..... 34
3.1.7 First plot of $f(x)$ ..... 35
3.1.8 $\quad$ Better plot of $f(x)$ ..... 35
4.1.1 Direction-field defined by equation 4.1.1 on page 41 ..... 42
4.1.2 $\quad$ The Logistic Curve ..... 45
4.1.3 Output of the Runge-Kutta algorithm ..... 48
4.1.4 Plot of two solutions ..... 49
4.2.1 Plot of rabbits versus foxes ..... 51
4.2.2 Rabbits and foxes ..... 51
4.3.1 First three terms ..... 56
4.3.2 First 10 terms ..... 57
4.3.3 Comparison of first 10 with $\mathrm{f}(\mathrm{x})$ ..... 57
4.3.4 The first 100 terms ..... 57
4.3.5 Periodicity of a Fourier series ..... 58
4.3.6 Gibbs Phenomena ..... 59
4.4.1 $\quad \psi(x, .01)$ ..... 61
4.4.2 $\psi(x, .02)$ ..... 61
4.4.3 $\quad \psi(x, .1)$ ..... 62
4.4.4 $\psi(x, 1)$ ..... 62
4.5.1 An example of plot3d ..... 63
4.5.2 with_slider_draw ..... 63
4.5.3 Evolution of the heat equation ..... 63
4.6.1 "Realistic" plucking function ..... 68
4.6.2 The extended plucking function ..... 68
4.6.3 Initial position of a two dimensional membrane ..... 71
4.6.4 First three terms of a two-dimensional Fourier series ..... 72
4.6.5 After . 4 time units ..... 73
5.1.1 Fourier transform of $f(x)$ ..... 77
5.3.1 Harmonic oscillator ..... 82
5.3.2 Simple harmonic motion ..... 83
5.3.3 Forced harmonic motion ..... 84
5.3.4 Discontinuous driving force ..... 86
6.1.1 Model for Legendre polynomials ..... 88
6.1.2 The first six Legendre polynomials ..... 89
6.1.3 First 5 terms of a Legendre series ..... 90
6.1.4 First 20 terms of a Legendre series ..... 91
6.2.1 The first four Chebyshev polynomials ..... 92
6.2.2 First 20 terms of a Chebyshev expansion ..... 93
6.2.3 Weight-function for Chebyshev expansions ..... 94
6.2.4 Laguerre polynomials ..... 94
6.2.5 Expansion of $f(x)$ in 100 Laguerre polynomials ..... 95
6.2.6 Hermite polynomials ..... 97
7.1.1 Code for a reduced echelon matrix ..... 105
7.3.1 Projection of a vector onto another ..... 110
7.3.2 Least squares fit ..... 113
7.3.3 Linear regression ..... 114
7.3.4 "Formula" for prime numbers ..... 116
7.4.1 A sample web ..... 125
7.6.1 Feasible region ..... 133
7.6.2 Linear programming solution ..... 134
8.1.1 The harmonic numbers ..... 147
8.2.1 The Gregory-Newton series ..... 150
8.2.2 Polynomial giving the first 10 primes ..... 151
8.2.3 Prime polynomial plot ..... 152
10.1.1 A simple robot arm ..... 163
10.1.2 Reaching a point ..... 165
10.2.1 A more complicated robot arm ..... 166
11.1.1 Turning radius=30 ..... 178
11.1.2 Turning radius=10 ..... 179
11.1.3 Bond far away ..... 179
11.1.4 Gimbel problem ..... 180
11.1.5 Solution to the Gimbel Problem ..... 180
11.2.1 Naive pursuit algorithm ..... 184
11.2.2 Rock speed 30 ..... 185
11.2.3 Predictive algorithm with rock speed 30 ..... 187
12.1.1 The $\Gamma$-function ..... 190
12.1.2 Plot of $|\Gamma(z)|$ ..... 191
12.2.1 Pendulum ..... 193
12.2.2 Jacobi functions ..... 196
12.2.3 Plot of $\operatorname{sn}(x, 9)$ ..... 196
12.2.4 Plot of $\mathrm{cn}(x, .9)$ ..... 197
12.3.1 First three Bessel J-functions ..... 200
12.3.2 First three Bessel Y-functions ..... 200
12.4.1 The Airy Functions ..... 202
12.5.1 The li-function ..... 203
12.5.2 The Ei-function ..... 204
12.5.3 $\quad E_{1}$-function ..... 205
12.5.4 The sine-integral ..... 205
12.5.5 The cosine-integral ..... 206
12.6.1 The Lambert $W$ function ..... 208
12.6.2 The Lambert function $W_{-1}(z)$ ..... 208
13.1.1 The contour, C ..... 212
13.2.1 Plot of $R(x)$ ..... 222
13.2.2 Approximate $\pi(x)$ ..... 223
13.2.3 First 100 primes (approximately) ..... 224
F.1.1 High-level plot example ..... 253
F.1.2 Mixed plot-types ..... 254
F.1.3 Plot example 1 ..... 255
F.1.4 Plot example 2 ..... 255
F.1.5 Parametric plot 1 ..... 256
F.1.6 Code for mixed parametric plot ..... 257
F.1.7 Mixed parametric plot ..... 257
F.1.8 Contour plot ..... 258
F.2.1 A 3d plot ..... 258
F.2.2 A 3d plot with mesh ..... 259
F.2.3 Plot with elevation 0 ..... 259
F.2.4 Plot using palette ..... 259
F.2.5 Plot with a color palette ..... 260
F.2.6 Plot with a color-bar ..... 260
F.3.1 The Mandelbrot set ..... 261
F.5.1 The with_slider_draw command ..... 262
F.5.2 Basic draw-command ..... 263
F.5.3 Two-column plot ..... 265
F.5.4 Drawing two plots in one command ..... 265
F.5.5 Drawings with two columns ..... 265
F.5.6 Multiple functions in the same scene ..... 267
F.5.7 The trefoil knot ..... 268
F.5.8 Output of exercise plot ..... 273
F.5.9 Plot of ellipse,same_xy ..... 282
F.5.10 Plot without same_xy ..... 283

## Adventures with Mathematical Software

## CHAPTER 1

## Introduction

#### Abstract

"In the broad light of day, mathematicians check their equations and their proofs, leaving no stone unturned in their search for rigour. But at night, under the full moon, they dream, they float among the stars and wonder at the miracle of the heavens. They are inspired.

Without dreams there is no art, no mathematics, no life." - Sir Michael Atiyah, Notices of the AMS, January 2010, page 8.

### 1.1. Installation and first steps

Mathematical software development has made great strides in recent decades, and one of the most powerful systems is free and open-source. It is a modernized form of the Macsyma system developed from 1968 to 1982 at MIT's Project MAC. The original system remained available to academics and US government agencies, and was distributed by the US Department of Energy (DOE). That version, DOE Macsyma, was maintained by Bill Schelter, a professor of mathematics at the University of Texas at Austin.

Under the name of Maxima, it was released under the GPL in 1999, and remains under active maintenance.

Versions of it exist for Linux, Windows, and the MacOS, and FreeBSD (see the web site https://maxima.sourceforge.io/. For other systems, you can download the source code and try to compile it.

The original Maxima had a command-line interface. Professor Schelter developed a rudimentary GUI interface. This was further improved by the wxMaxima project and now includes menus for many of the maxima commands and the ability to save one's work in a kind of notebook.

Your first assignment is to download wxMaxima and install this on the system of your choice (Maxima is bundled with most distributions of wxMaxima).
(1) In windows, you can download a version of it from http://wxmaxima-developers.github.io/wxmaxima/.
(2) In Linux and the three BSD's ${ }^{1}$, pre-packaged versions of wxMaxima are available that you can install if you have root access. After it is installed, you can run it from your applications menu or in any directory by typing wxmaxima

[^0](3) If you don't have root access or your distribution doesn't support it, you can download the "Applimage" version of wxMaxima from the web site listed above and install it in your user account by following the instructions. This image contains Maxima and all other dependencies.

After starting up wxMaxima, you will notice a number of menus:
File: this is self-explanatory. It allows you to save notebooks and open ones you have saved.
Edit: also self-explanatory. The copy menu-items are significant. Copy-astext copies a formula in a format that can be input to Maxima. Copy-as-LaTex copies it in a format suitable for inclusion in a TeX typesetting document. Copy-as-mathml copies it in a format suitable for web pages. Copy-as-image is suitable for pasting into a word document or web pages that can't be viewed by a mathmlaware web browser.
View: this controls which palettes and menus you see. Play with it to see what it does!
Cell: this is important! Maxima statements are called cells, and this executes them (as well as manipulating them in other ways).
Maxima: this interacts with the Maxima program in various ways.
Equations: this contains Maxima commands to solve equations or differential equations.
Matrix: a menu containing commands for creating and manipulating matrices.
Calculus: a menu containing commands to differentiate and integrate functions, among other things.
Simplify: an important menu containing commands to simplify or expand expressions and manipulate complex numbers.
List: commands to manipulate lists.
Plot: commands to create plots.
Numeric: contains commands related to numeric computations.
Help: self-explanatory.
\%: this is not a menu item, but is very important nevertheless. This symbol represents the value of the last computation Maxima performed. Most menu commands act on this by default (although you can override this easily).

Go to the menu marked 'New' in the upper right portion of the screen and select a new Maxima session (there are several other options available). Type $1+1$ and click Cell®Evaluate Cell(s) to get ' 2 '. Amazing! This software can add 1 and 1 . We can also operate with numbers using '*' for multiplication, '/' for division, and ' $\wedge$ ' for raising to a power.

See table 1.1.1 on the next page, so the expression $1 / 2 * a^{\wedge} 2-3=0$ has implied parentheses $\left((1 / 2) *\left(\mathrm{a}^{\wedge} 2\right)\right)-3=0$. Operations at the same priority are evaluated from left to right, so $3 / 4 / 5=3 /(4 * 5)=3 / 20$.

At this point, it is a good idea to save your notebook and give it a name other than 'Untitled'. Go to the 'File' menu and select 'Save As'.

| Operator |  |
| :---: | :---: |
| $\wedge$ | Exponentiation |
| $/^{*}, .$, | Division, multiplication, matrix-multiplication |
| ,+- | Addition, subtraction |
| $:$ | Assignment |
| $=, \#,<,\rangle,<=,>=$ | Equal, not equal, greater than, less than, greater or equal |
| not | boolean not |
| and | boolean and |
| or | boolean or |

TABLE 1.1.1. Hierarchy of operations

Maxima can factor numbers: type factor(121) and click Cell $\triangleright$ Evaluate Cell(s) to get $11^{2}$. For something more challenging, try factor(123456789) to get $3^{2} 36073803$.

Maxima saves fractions in their lowest form. If you type 128/256, Maxima will come back with 1/2.

Maxima had the basic abs-function built in that computes absolute value:

$$
\begin{aligned}
\boldsymbol{a b s}(2) & =2 \\
\boldsymbol{a b s}(-2) & =2
\end{aligned}
$$

In general, Maxima has examples of its commands built into it. The general format of the example-command is

```
example(command)
```

For instance, try typing and click example(factor) and click Cell $\triangleright$ Evaluate Cell(s).

This may be used in other commands to refer to that output. For instance, suppose you type $2^{\wedge} 100$ and click Cell $\triangleright$ Evaluate Cell(s) to get

$$
1267650600228229401496703205376
$$

Now you can type factor (\%) and click Cell $\triangleright$ Evaluate Cell(s) to get $2^{100}$.
To get an idea of the raw computing power of Maxima, consider the factorial function. Recall that factorials are defined by

$$
n!=n \times(n-1) \times(n-2) \times \cdots \times 1
$$

The Maxima command for computing this is n ! or factorial ( n ). Try typing 100! or 1000! and clicking on Cell $\triangleright$ Evaluate Cell(s).

Factorials like $n$ ! represent the number of ways of arranging $n$ distinct objects: Given $n$ slots, the first object can go into any one of them. After it has been placed, there are $n-1$ slots left for the second object, and $n-2$ for the third, and so on.

Maxima also has a binomial-command given by

$$
\operatorname{binomial}(n, m)=\frac{n!}{m!(n-m)!}
$$

It also has a mathematical significance: it represents the number of ways of selecting a set of $m$ objects from a set of $n$ distinct objects. The numerator is all possible arrangements of the original $n$ objects. Since we don't care what order the $m$ objects we've selected are in (because this is a set of $m$ objects), we divide out by the ways of arranging these $m$ objects. Since we really don't care what order the $n-m$ objects we didn't select are in, we also divide out by ( $\mathrm{n}-\mathrm{m}$ )!.

The float-command gives the numeric value of a quantity in scientific notation.

> The word float is part of computing history. Early computers could only work with integers. When computers were built that could handle numbers in scientific notation, the numbers were called floating-point because the decimal point could "float" into any position. In Maxima, float numbers use the computer's intrinsic ability to do floating-point arithmetic. Maxima also has a bfloat-command with floating point arithmetic implemented in software. These numbers could potentially have thousands of significant digits. A bfloat-number followed by bnn means the number is to be multiplied by $10^{n n}$.

If you type 123456789/987654321 and click CellゅEvaluate Cell(s) you get the fraction in its lowest terms: 13717421/109739369. If you type bfloat(123456789/987654321) and click Cell $\triangleright$ Evaluate Cell(s), you get 0.124999998860938 .

The Numeric menu has a Bigfloat-precision option that specifies the number of digits to use. If you set this to 100, typing bfloat(\%pi) and selecting Cell $\triangleright$ Evaluate Cell(s) gives
3.14159265358979323846264338327950288419716939937510 5820974944592307816406286208998628034825342117068

Maxima has predefined mathematical constants such as $e$ and $\pi$ : typing bfloat(\%e) and selecting Cell $\triangleright$ Evaluate Cell(s) produces 2.71828182845905: see Appendix B on page 231 for a list of them including inf for infinity ${ }^{2}$.

[^1]

Figure 1.1.1. The complex plane

Identifiers in maxima are strings of: lower- and upper-case letters, digits, and '_'. They must not begin with a digit. Examples: 'set1', 'total_series', 'accum'. They are case-sensitive and must not equal any Maxima keyword:

| integrate | next | from | diff |
| :---: | :---: | :---: | :---: |
| in | at | limit | sum |
| for | and | elseif | then |
| else | do | or | if |
| unless | product | while | thru |
| step | block | return | derivative |

In Maxima, \%i represents $\sqrt{-1}$ and we can compute with complex numbers. Recall that complex numbers can be either in a rectangular form like $a+b i$ or a polar form like $r e^{i \theta}$ - see figure 1.1.1. Maxima has commands to convert numbers between these forms: the rectform-command or menu-item Simplify $\triangleright$ Complex Simplification $\triangleright$ Convert to Rectform or the polform-command or menu-item

| Simplify $\triangleright$ Complex Simplification $\triangleright$ Convert to Polarform. | Typing |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
| $(2+3 * \%$ i $) /(4+5 * \%$ i) | and | clicking | Cell $\triangleright$ Evaluate Cell(s) $)$ | causes | Maxima to come back with $\frac{3 \% i+2}{5 \% i+4}$. Typing the rectform-command or menu-item Simplify $\triangleright$ Complex Simplification $\triangleright$ Convert to Rectform gives $\frac{2 \% i}{41}+\frac{23}{41}$. Typing the polarform-command or menu-item Simplify $\triangleright$ Complex Simplification $\triangleright$ Convert to Polarform gives

$$
\frac{\sqrt{13} \% e^{\% i \arctan \left(\frac{2}{23}\right)}}{\sqrt{41}}
$$

Typing $\% \mathrm{e}^{\wedge}(\% \mathrm{pi} \% \% \mathrm{i})$ and clicking Cell $\triangleright$ Evaluate Cell(s) results in -1 , reproducing Euler's famous formula

$$
e^{\pi i}=-1
$$

and typing $\% \mathrm{e}^{\wedge}(\mathrm{x} * \% \mathrm{i})$ and the rectform-command or menu-item Simplify $\triangleright$ Complex Simplification $\triangleright$ Convert to Rectform gives De Moivre's famous formula

$$
\begin{equation*}
\% i \sin (x)+\cos (x) \tag{1.1.1}
\end{equation*}
$$

As you might expect, Maxima has basic functions like realpart and imagpart that extracts these aspects of complex numbers

$$
\begin{aligned}
\operatorname{realpart}(a+b * \% i) & =a \\
\operatorname{imagpart}(a+b * \% i) & =b
\end{aligned}
$$

Unfortunately, the abs-function doesn't quite know how to handle complex numbers:

$$
\boldsymbol{\operatorname { a b s }}(a+b * \% i)=|a+b * \% i|
$$

For this purpose, we need the closely-related cabs-function ("complex" absolute value)

$$
\operatorname{cabs}(a+b * \% i)=\sqrt{b^{2}+a^{2}}
$$

Leonhard Euler (1707-1783) was, perhaps, the greatest mathematician of all time. Although he was born in Switzerland, he spent most of his life in St. Petersburg, Russia and Berlin, Germany. He originated the notation $f(x)$ for a function and made contributions to mechanics, fluid dynamics, optics, astronomy, and music theory. His final work, "Treatise on the Construction and Steering of Ships," is a classic whose ideas on shipbuilding are still used to this day.

To do justice to Euler's life would require a book considerably longer than the current one - see the article [16]. His collected works fill more than 70 volumes and, after his death, he left enough manuscripts behind to provide publications to the Journal of the Imperial Academy of Sciences (of Russia) for 47 years.

Typing $\% \mathrm{e}^{\wedge(\% \mathrm{pi} * \% i / 3) \text { and clicking } \quad \text { Cell } \triangleright \text { Evaluate Cell(s) gives }}$ a cube root of -1 , i.e., $\frac{\sqrt{3} i}{2}+\frac{1}{2}$. We can verify this claim by typing $(1 / 2 * \% i * \operatorname{sqrt}(3)+1 / 2)^{\wedge} 3$. Unfortunately, Maxima just comes back with $\left(\frac{\sqrt{3} i}{2}+\frac{1}{2}\right)^{3}$.

What are we to do? Maxima has a command expand() that causes it to eliminate parentheses as much as possible and multiply factors out. Typing expand $\left((1 / 2 * \% \mathrm{i} * \mathrm{sqrt}(3)+1 / 2)^{\wedge} 3\right)$ or clicking Simplify $\triangleright$ Expand Expression results in -1 .

## EXERCISES.

1. From a standard 52 -card deck of playing cards, how many 5 -card Poker hands are possible?
2. Write in the form $a+b i$

$$
\frac{2}{3+i}
$$

3. Write in the form $a+b i$

$$
3 i+\frac{1}{1-i}
$$

4. Find equations for $\sin n \theta$ and $\cos n \theta$ in terms of $\sin \theta$ and $\cos \theta$. Hint: use de Moivre's Formula ( 1.1.1 on the facing page) and the binomial theorem.

## CHAPTER 2

## Number theory

"Mathematics is the queen of sciences and number theory is the queen of mathematics. She often condescends to render service to astronomy and other natural sciences, but in all relations she is entitled to the first rank."

- Carl Friedrich Gauss, see [47].

### 2.1. Introduction

People not interested in number theory can skip this chapter; none of the others depend on it.

Number theory is the study of integers. On the surface this makes it seem almost laughably simple, but some of the most difficult and complex problems in all of mathematics belong to number theory. For instance, Fermat's Last Theorem (stated in 1637):

The equation

$$
a^{n}+b^{b}=c^{n}
$$

has no solutions in integers with $a, b, c>0$ and $n>2$. was only proved in 1995 by Andrew Wiles.

Pierre de Fermat (1607-1665) was a French mathematician who is given credit for early developments that led to infinitesimal calculus, including his technique of adequality ${ }^{a}$. He is recognized for his discovery of an original method of finding the greatest and the smallest ordinates of curved lines, which is analogous to that of differential calculus, and his research into number theory. He made notable contributions to analytic geometry, probability, and optics. He is best known for his Fermat's principle for light propagation and his Fermat's Last Theorem in number theory, which he described in a note at the margin of a copy of Diophantus's Arithmetica.
${ }^{a}$ For finding maxima and minima of functions.
The famous Riemann Hypothesis (discussed in chapter 13 on page 211) is still unsolved.

Applied mathematicians regarded number theory as a subject only of theoretical interest ${ }^{1}$. This state of affairs changed in the 1960's when powerful new systems of cryptography were discovered that use number theory. Today, the National Security Agency (responsible for secure communications) employs more number theorists than any university.

[^2]We will begin by reviewing some very basic material.
Most people learned the following result in grade school - long division with a quotient and remainder:

Proposition 2.1.1. Let $n$ and $d$ be real numbers. Then it is possible to write

$$
n=q \cdot d+r
$$

where $q$ is an integer and $0 \leq r<d$. If $r=0$, we say that $d \mid n$ - stated " $d$ divides $n "$. The negation of this is $d \nmid n$ ( d doesn't divide $n$ ).

Maxima can compute this with the mod-command: type $\bmod (987654321,123456789)$; and $\quad$ Cell $\triangleright$ Evaluate Cell(s) to get the remainder of dividing 987654321 by 123456789 , namely 9 .

Although this definition usually requires $n$ and $d$ to be integers, the Maxima command works for real numbers as well: $\boldsymbol{\operatorname { m o d }}(1.5,1)$; produces .5 . Essentially,

$$
\begin{equation*}
\bmod (a, b)=a-\left\lfloor\frac{a}{b}\right\rfloor \cdot b \tag{2.1.1}
\end{equation*}
$$

The division algorithm gives rise to the concept of greatest common divisor.

Definition 2.1.2. Let $n$ and $m$ be positive integers. The greatest common divisor of $n$ and $m$, denoted $\operatorname{gcd}(n, m)$, is the largest integer $d$ such that $d \mid n$ and $d \mid m$. The least common multiple of $n$ and $m$, denoted $1 \mathrm{~cm}(n, m)$, is the smallest positive integer $k$ such that $n \mid k$ and $m \mid k$.

Since 0 is divisible by any integer, $\operatorname{gcd}(n, 0)=\operatorname{gcd}(0, n)=n$.
There is a very fast algorithm for computing the greatest common divisor due to Euclid - see [12, 13].

REMARK. Euclid's original formulation was geometric, involving linesegments. Given two line-segments of lengths $r_{1}$ and $r_{2}$, it found a real number $r$ such that

$$
\frac{r_{1}}{r}, \frac{r_{2}}{r} \in \mathbb{Z}
$$

An ancient proof of the irrationality of $\sqrt{2}$ showed that this process never terminates if one of the line-segments is of unit length and the other is the diagonal of a unit square.

As trivial as proposition 2.1.1 appears to be, it allows us to prove Bézout's Identity:

Lemma 2.1.3. Let $n$ and $m$ be positive integers. Then there exist integers $u$ and $v$ such that

$$
\begin{equation*}
\operatorname{gcd}(n, m)=u \cdot n+v \cdot m \tag{2.1.2}
\end{equation*}
$$

REmARK. Bézout proved this identity for polynomials - see [2]. However, this statement for integers can be found in the earlier work of Claude Gaspard Bachet de Méziriac (1581-1638) - see [22].

After loading via load("gcdex"), the Maxima function igcdex(n, k) computes the greatest common divisor and the values of $u, v$ that appear in equation 2.1.2 on the preceding page.

For example
load ("gcdex ");
igcdex (12345,98765432)
returns

$$
[-39546175,4943,1]
$$

where $\operatorname{gcd}(12345,98765432)=1$ and

$$
-39546175 \cdot 12345+4943 \cdot 98765432=1
$$

Étienne Bézout (1730-1783) was a French algebraist and geometer credited with the invention of the determinant (in [4]).

Definition 2.1.4. A prime number is an integer that is not divisible by any integer other than 1 or $( \pm)$ itself.

The Maxima commands regarding primes are:
$\triangleright \operatorname{primep}(n)$ returns true when $n$ is a prime and false otherwise. The parameter primep_number_of_tests determines how many types of tests for primality will be performed. The default is 25 .
$\triangleright \operatorname{primes}(n, m)$ - returns a list of all primes, $p$, such that $n \leq p \leq m$. For instance

$$
\text { primes }(2,20)
$$

returns

$$
[2,3,5,7,11,13,17,19]
$$

$\triangleright$ prev_prime $(n)$ — returns the largest prime $<n$.
$\triangleright$ next_prime $(n)$ - returns the smallest prime $>n$.
It is well-known that integers can be factored into powers of primes in a unique way (see [40, chapter 3]:

Lemma 2.1.5. Let $n$ be a positive integer and let

$$
\begin{align*}
n & =p_{1}^{\alpha_{1}} \cdots \cdots p_{k}^{\alpha_{k}} \\
& =q_{1}^{\beta_{1}} \cdots \cdots q_{\ell}^{\beta_{\ell}} \tag{2.1.3}
\end{align*}
$$

be factorizations into powers of distinct primes. Then $k=\ell$ and there is a reordering of indices $f:\{1, \ldots, k\} \rightarrow\{1, \ldots, k\}$ such that $q_{i}=p_{f(i)}$ and $\beta_{i}=\alpha_{f(i)}$ for all ifrom 1 to $k$.

The Maxima function ifactors( n ) determines the unique factorization of $n$ :
ifactors (123456789);
returns

$$
[[3,2],[3607,1],[3803,1]]
$$

showing that

$$
123456789=3^{2} \cdot 3607 \cdot 3803
$$

In this case, the factor-command also works.
Unique factorization also leads to many other results:
PROPOSITION 2.1.6. Let $n$ and $m$ be positive integers with factorizations

$$
\begin{aligned}
n & =p_{1}^{\alpha_{1}} \cdots p_{k}^{\alpha_{k}} \\
m & =p_{1}^{\beta_{1}} \cdots p_{k}^{\beta_{k}}
\end{aligned}
$$

Then $n \mid m$ if and only if $\alpha_{i} \leq \beta_{i}$ for $i=1, \ldots, k$ and

$$
\begin{aligned}
\operatorname{gcd}(n, m) & =p_{1}^{\min \left(\alpha_{1}, \beta_{1}\right)} \cdots p_{k}^{\min \left(\alpha_{k}, \beta_{k}\right)} \\
\operatorname{lcm}(n, m) & =p_{1}^{\max \left(\alpha_{1}, \beta_{1}\right)} \cdots p_{k}^{\max \left(\alpha_{k}, \beta_{k}\right)}
\end{aligned}
$$

Consequently

$$
\begin{equation*}
\operatorname{lcm}(n, m)=\frac{n m}{\operatorname{gcd}(n, m)} \tag{2.1.4}
\end{equation*}
$$

Definition 2.1.7. If $n>0$ is an integer, two integers $r$ and $s$ are congruent modulo $n$, written

$$
r \equiv s \quad(\bmod n)
$$

if

$$
n \mid(r-s)
$$

REMARK. It is also common to say that $r$ and $s$ are equal modulo $n$. The first systematic study of these type of equations was made by Gauss in his Disquistiones Arithmeticae ([15]). Gauss wanted to find solutions to equations like

$$
a_{n} x^{n}+\cdots+a_{1} x+a_{0} \equiv 0 \quad(\bmod p)
$$

In Maxima terms, $r \equiv s(\bmod n)$ if and only if $\bmod (r, n)=\boldsymbol{\operatorname { m o d }}(s, n)$.
Proposition 2.1.8. Equality modulo $n$ respects addition and multiplication, i.e. if $r, s, u, v \in \mathbb{Z}$ and $n \in \mathbb{Z}$ with $n>0$, and

$$
\begin{align*}
r & \equiv s \\
& (\bmod n)  \tag{2.1.5}\\
u & (\bmod n)
\end{align*}
$$

then

$$
\begin{align*}
r+u & \equiv s+v \quad(\bmod n) \\
r \cdot u & \equiv s \cdot v \quad(\bmod n) \tag{2.1.6}
\end{align*}
$$

This elementary result has some immediate implications:
EXAMPLE. Show that $5 \mid\left(7^{k}-2^{k}\right)$ for all $k \geq 1$. First note, that $7 \equiv 2$ $(\bmod 5)$. Equation 2.1.6, applied inductively, implies that $7^{k} \equiv 2^{k}(\bmod 5)$ for all $k>1$.

Definition 2.1.9. If $n$ is a positive integer, the set of equivalence classes of integers modulo $n$ is denoted $\mathbb{Z}_{n}$.

Remark. It is not hard to see that the size of $\mathbb{Z}_{n}$ is $n$ and the equivalence classes are represented by integers

$$
\{0,1,2, \ldots, n-1\}
$$

Proposition 2.1.8 on the preceding page implies that addition and multiplication is well-defined in $\mathbb{Z}_{n}$. The Maxima command zn_add_table $(n)$ returns a table of $\mathbb{Z}_{n}$ with the addition-operation. For instance:

```
zn_add_table(8);
```

returns table 2.1.1.

$$
\left(\begin{array}{llllllll}
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 \\
1 & 2 & 3 & 4 & 5 & 6 & 7 & 0 \\
2 & 3 & 4 & 5 & 6 & 7 & 0 & 1 \\
3 & 4 & 5 & 6 & 7 & 0 & 1 & 2 \\
4 & 5 & 6 & 7 & 0 & 1 & 2 & 3 \\
5 & 6 & 7 & 0 & 1 & 2 & 3 & 4 \\
6 & 7 & 0 & 1 & 2 & 3 & 4 & 5 \\
7 & 0 & 1 & 2 & 3 & 4 & 5 & 6
\end{array}\right)
$$

Table 2.1.1. Addition table for $\mathbb{Z}_{8}$

It is interesting to speculate on when a number has a multiplicative inverse modulo $n$. It turns out that:

Proposition 2.1.10. If $n>1$ is an integer and $x \in \mathbb{Z}_{n}$, then there exists $y \in \mathbb{Z}_{n}$ with

$$
x \cdot y \equiv 1 \quad(\bmod n)
$$

if and only if $\operatorname{gcd}(x, n)=1$. When this is true, we say that $x$ is relatively prime to $n$.

Because of this, we are generally only interested in the elements $x \in \mathbb{Z}_{n}$ that are relatively prime to $n$. The set of such numbers is denoted $\mathbb{Z}_{n}^{\times}$, where the superscript $\times$ indicates that we're considering the elements of $\mathbb{Z}_{n}$ under multiplication rather than addition. Maxima has a command for computing the multiplication table for $\mathbb{Z}_{n}^{\times}$: zn_mult_table $(n)$. For instance

```
zn_mult_table(8);
```

produces the table in 2.1.2 on the next page.
We also have other commands for doing modular arithmetic:
$\triangleright$ power_mod $(a, n, m)$ - computes $a^{n}(\bmod m)$. Note: there are algorithms for computing powers modulo another number that are much faster than simply raising the number to that power.
$\triangleright \operatorname{inv} \_\bmod (n, m)-$ computes $n^{-1}(\bmod m)$, if it exists (i.e., if $\operatorname{gcd}(n, m)=1)$, and false otherwise.
This section would not be complete without mention of the famous:

$$
\left(\begin{array}{llll}
1 & 3 & 5 & 7 \\
3 & 1 & 7 & 5 \\
5 & 7 & 1 & 3 \\
7 & 5 & 3 & 1
\end{array}\right)
$$

TABLE 2.1.2. Multiplication table for $\mathbb{Z}_{8}^{\times}$

THEOREM 2.1.11 (Chinese Remainder Theorem). If $n_{1}, \ldots, n_{k}$ are a set of positive integers with $\operatorname{gcd}\left(n_{i}, n_{j}\right)=1$ for all $1 \leq i<j \leq k$, then the equations

$$
\begin{array}{cc}
x \equiv a_{1} \quad\left(\bmod n_{1}\right) \\
\vdots & \\
x \equiv a_{k} \quad\left(\bmod n_{k}\right)
\end{array}
$$

have a unique solution modulo $\prod_{i=1}^{k} n_{i}$.
Remark. The Chinese Remainder Theorem was first published sometime between the 3rd and 5th centuries by the Chinese mathematician Sun Tzu (not to be confused with the author of "The Art of Warfare").

Naturally, Maxima has a command that implements this: In the notation of theorem 2.1.11, the command chinese $\left(\left[a_{1}, \ldots, a_{k}\right],\left[n_{1}, \ldots, n_{k}\right]\right)$ returns $x$. If any of the conditions of theorem 2.1.11 are not met, it returns false.

## Exercises.

1. If $n$ and $m$ are two integers with $\operatorname{gcd}(n, m)=1$, what can you say about the primes that appear in their factorizations?
2. If $n$ and $m$ are two integers with $\operatorname{gcd}(n, m)=1$, show that $\mathbb{Z}_{n \cdot m}^{\times}=$ $\mathbb{Z}_{n}^{\times} \times \mathbb{Z}_{m}^{\times}$(the right side of this consists of pairs $(a, b)$, where $a \in \mathbb{Z}_{n}^{\times}$and $b \in \mathbb{Z}_{m}^{\times}$). Hint: use the Chinese Remainder Theorem.

### 2.2. Euler's totient function

Definition 2.2.1. If $n$ is a positive integer then

$$
\phi(n)
$$

is the number of generators of $\mathbb{Z}_{n}$ - or the number of elements in $\mathbb{Z}_{n}^{\times}$, or
$\triangleright$ If $n>1$ it is the number of integers, $d$, with $1 \leq d<n$ with $\operatorname{gcd}(d, n)=1$.
$\triangleright$ If $n=1$, it is equal to 1 .

This is called the Euler $\phi$-function. Euler also called it the totient. The Maxima command for computing this is called totient $(n)$.

REMARK. If $p$ is a prime number, then $\phi(p)=p-1$ since the integers $1 \leq i \leq p-1$ are all relatively prime to $p$.

Exercise 2 on the facing page shows that, if $n$ and $m$ are integers with $\operatorname{gcd}(n, m)=1$, then

$$
\begin{equation*}
\phi(m n)=\phi(n) \phi(m) \tag{2.2.1}
\end{equation*}
$$

This $\phi$-function has some interesting applications
Proposition 2.2.2. If $n$ and $m$ are integers $>1$ with $\operatorname{gcd}(n, m)=1$, then

$$
\begin{equation*}
m^{\phi(n)} \equiv 1 \quad(\bmod n) \tag{2.2.2}
\end{equation*}
$$

It follows that, for any integers $a$ and $b$

$$
\begin{equation*}
m^{a} \equiv m^{b} \quad(\bmod n) \tag{2.2.3}
\end{equation*}
$$

whenever

$$
a \equiv b \quad(\bmod \phi(n))
$$

REMARK. Fermat proved this for $n$ a prime number - in that case, it is called Fermat's Little Theorem.

## ExERCISES.

1. Why is $7^{999} \equiv 7^{-1}(\bmod 100)$ ?

### 2.3. Public-key cryptography

"Well, a regular code is like a strongbox with a key. You lock your message in it and nobody can read it without the key."
"I understand. But Ed needs the key to read the messages, right? How do you get it to him without the bad guys also seeing it?"
"That's the beauty of this system. It's like a magic box that comes with two different keys. When you lock it with one key, only the other key can open it."
"You can't use the original one?" she said.
"No," I replied. "So, I send Ed one key and keep the other for myself. Even if the bad guys get his key, they can't use it to decode my messages. Only the one I keep will do that."

- Constance Fairchild, in the novel Bloodline (with the author's permission). See [41].
The idea of a public-private key cryptosystem is attributed to Whitfield Diffie and Martin Hellman, who published the concept in 1976.

Bailey Whitfield 'Whit' Diffie (1944-) An American cryptographer and mathematician and one of the pioneers of public-key cryptography along with Martin Hellman and Ralph Merkle. Diffie and Hellman's 1976 paper, [11], introduced a radically new method of distributing cryptographic keys, that helped solve key distribution - a fundamental problem in cryptography. They lacked a good implementation of their ideas.

Martin Edward Hellman (1945-) is an American cryptographer and mathematician, best known for his involvement with public key cryptography in cooperation with Whitfield Diffie and Ralph Merkle. Hellman is a longtime contributor to the computer privacy debate, and has applied risk analysis to a potential failure of nuclear deterrence.
Hellman was elected a member of the National Academy of Engineering in 2002 for contributions to the theory and practice of cryptography.

In 1977, Ron Rivest, Adi Shamir and Leonard Adleman, described an efficient algorithm for public key encryption based on proposition 2.2.2 on the previous page. A description of the algorithm was published in August 1977, in Scientific American magazine's Mathematical Games column ${ }^{2}$.

Clifford Cocks, an English mathematician working for the British intelligence agency Government Communications Headquarters (GCHQ), described an equivalent system in an internal document in 1973. His description was classified until the RSA algorithm appeared.

Ronald Linn Rivest (1945-) is a cryptographer and computer scientist whose work has spanned the fields of algorithms and combinatorics, cryptography, machine learning, and election integrity. He is an Institute Professor at the Massachusetts Institute of Technology (MIT) and a member of MIT's Department of Electrical Engineering and Computer Science and its Computer Science and Artificial Intelligence Laboratory.
Along with Adi Shamir and Len Adleman, Rivest is one of the inventors of the RSA algorithm. He is also the inventor of the symmetric key encryption algorithms RC2, RC4, and RC5, and co-inventor of RC6. (RC stands for "Rivest Cipher". He also devised the MD2, MD4, MD5 and MD6 cryptographic hash functions.

> Adi Shamir (1952-) is an Israeli cryptographer. He is a co-inventor of the Rivest-Shamir-Adleman (RSA) algorithm (along with Ron Rivest and Len Adleman), a co-inventor of the Feige-Fiat-Shamir identification scheme (along with Uriel Feige and Amos Fiat), one of the inventors of differential cryptanalysis and has made numerous contributions to the fields of cryptography and computer science

Leonard Adleman (1945-) is an American computer scientist. He is one of the creators of the RSA encryption algorithm, for which he received the 2002 Turing Award. He is also known for the creation of the field of DNA computing.

[^3]The basic idea:
Let $p$ and $q$ be two large ( 30 digits or more) primes, and let $n=p q$ so $\phi(n)=(p-1)(q-1)$. Now let $a, b$ be integers such that

$$
a b \equiv 1 \quad(\bmod \phi(n))
$$

If $1 \leq x \leq n$ is any number, then

$$
\left(x^{a}\right)^{b}=x^{a b} \equiv x^{1} \quad(\bmod n)
$$

So, to encode $x$, raise it to the $a^{\text {th }}$ power $\bmod n$. The "encoded message" is $(n, y)$, where $y \equiv x^{a}(\bmod n)$. To "decode" the message, compute $y^{b} \bmod n$, resulting in the original $a$.

Make the value of $n$ and $a$ widely available. If anyone wants to send you a message, they raise it to the $a^{\text {th }}$ power $\bmod n$ and transmit it. When you receive it, you raise it to the $b^{\text {th }}$ power $\bmod n$ and retrieve the original message.
How would a malicious person crack this code? They know $a$ and $n$ because these numbers were widely publicized. If they could compute $\phi(n)$ it would be fairly easy ${ }^{3}$ to compute $b \equiv a^{-1}(\bmod \phi(n))$. So the whole problem of cracking this code boils down to computing $\phi(n)$, given $n$. It turns out that there's no known way of doing this without factoring $n$ to get $p$ and $q$.

The conventional way to factor numbers involves trying primes like $2,3, \ldots, 17$ and reducing the size of the number until it is manageable. Suppose the smallest prime that divides a number has 30 digits! Factoring that number will be quite difficult. Faster algorithms for factoring numbers have been discovered ${ }^{4}$, but they are not substantially faster in all cases.

This is called the RSA encryption algorithm after its developers' surnames. Since converting a long message to numbers and raising them to a high power is computationally expensive, the "messages" sent via this algorithm are usually keys for other, more conventional ciphers - which is why it's called a key-distribution algorithm.

Its security depends on the difficulty of factoring certain large numbers.
Nowadays, the RSA algorithm uses the Carmichael $\lambda$-function rather than the $\phi$-function:

Definition 2.3.1. If $n>1$ is an integer, the Carmichael function, $\lambda(n)$, is the smallest integer $1 \leq k \leq n$ such that

$$
a^{k} \equiv 1 \quad(\bmod n)
$$

for all $a \in \mathbb{Z}$ such that $\operatorname{gcd}(n, a)=1$.

[^4]If $p$ and $q$ are primes, it turns out that $\lambda(p \cdot q)=\operatorname{lcm}(p-1, q-1) \leq$ $(p-1)(q-1)$, and computing this still requires factoring $p \cdot q$. It's used these days simply because it is usually smaller than $\phi(p \cdot q)^{5}$.

Naturally, Maxima has a command for computing $\lambda(n)$ :

```
zn_carmichael_lambda(n)
```

For instance

```
totient(100)
```

returns 40, while

```
zn_carmichael_lambda(100)
```

returns 20.
We have the related command

```
zn_order(x,n)
```

which computes the lowest exponent $t$ such that

$$
x^{t} \equiv 1 \quad(\bmod n)
$$

The computation uses a factorization of $\phi(n)$ (i.e. totient(n)). Since this might be time-consuming (or practically impossible), the user can "help the command" by supplying such a factorization ${ }^{6}$ as the second parameter in the notation of ifactors.

So our cryptographic scheme involve the following steps:
(1) Choose two large prime numbers $q<p$. To make factoring harder, $p$ and $q$ should be chosen at random, be both large and have a large difference: If

$$
\frac{1}{2 q}\left(\frac{p-q}{2}\right)^{2}
$$

is small, Fermat factorization can easily factor $p \cdot q$ - see appendix D on page 235. For choosing the primes, the standard method is to choose random integers and test for primality (using prime_p in Maxima, for instance) until two primes are found. The primes $p$ and $q$ are kept secret.
(2) Compute $n=p q$. This product, $n$, is used as the modulus for both the public and private keys. Its length, usually expressed in bits, is the key length.
(3) Compute $\lambda(n)=\operatorname{lcm}(p-1, q-1)$.
(4) Choose an integer $e$ such that $2<e<\lambda(n)$ and $\operatorname{gcd}(e, \lambda(n))=1$. $e$ having a short bit-length and small Hamming weight (number of 1 's in its binary representation) results in more efficient encryption — the most commonly chosen value for $e$ is $2^{16}+1=65537$. The smallest (and fastest) possible value for $e$ is 3 , but such a small

[^5]value for $e$ has been shown to be less secure in some settings. The public key is the pair ( $n, e$ ). This is widely publicized.
(5) $e$ is released as part of the public key. Determine $d \equiv e^{-1}$ $(\bmod \lambda(n))$. The number, $d$, is kept secret as the private key exponent. The private key is $(n, d)$ - this is kept secret.

Claim. Everyone who has ever purchased something on the network has used a public key cryptosystem. The web server (for instance, the vendor selling things) generates a public and private key pair. Then it sends the public key to the web browser, which replies with an encrypted message containing a randomly generated key for a secure conventional cryptosystem (the message also includes a code for the desired type of conventional cryptosystem; most browsers and servers support many of them). The web server decrypts that and all further communication between the web server and the browser is encrypted via the conventional system using that key.

Another important application of public-key cryptosystems is in digital signatures. This passage from Bloodline says it all:
...Then use your private key to lock your message in the box.
Although your message is locked away, anyone can read it

- using your public key to unlock it. That's fine - this time, your aim wasn't to hide the message. The very fact that your public key works proves you locked the message in the box: Only the mate of the key that locked the magic box can unlock it...
- from the novel Bloodline (with the author's permission).

See [41].
In real life, a kind of summary of the message (a MD5-hash, for instance) is encrypted with the private key (not the whole message!) and sent along with the original message.

### 2.4. Diffie-Hellman-Merkle key exchange

> Ralph C. Merkle (1942-) is a computer scientist and mathematician. He is one of the inventors of public-key cryptography, the inventor of cryptographic hashing, and more recently a researcher and speaker on cryonics. Merkle is a renowned cryptographer, known for devising Merkle's Puzzles, co-inventing the Merkle-Hellman knapsack cryptosystem, and inventing cryptographic hashing (Merkle-Damgård construction) and Merkle trees. He received the IEEE Richard W. Hamming Medal in 2010 and has published works on molecular manipulation and self-replicating machines. He also serves on the board of directors for the cryonics organization Alcor Life Extension Foundation and appears in the science fiction novel The Diamond Age.

This is a variation on the public-key cryptography described in the last section, in that there is no private key. Let $n>1$ be an integer and consider the multiplicative set $\mathbb{Z}_{n}^{\times}$. This has $\phi(n)$ elements and

Definition 2.4.1. Given an integer, $n$, a primitive root modulo $n, x \in$ $\mathbb{Z}_{n}^{\times}$, is an element with the property that for any $y \in \mathbb{Z}_{n}^{\times}$there exists an integer $m$ such that $y=x^{m}(\bmod n)$.

REMARK. Primitive roots exist if $n=2,4, p^{k}$ or $2 p^{k}$ with $p$ a prime $>2$ — see [15] or [46].

Maxima has a command for computing primitive elements if they exist:
zn_primroot (n)
or false if they don't.
The parameter $\mathbf{z n}$ _primroot_limit determines how many attempts it will make (the default is 1000). The computation uses a factorization of $\phi(n)$ (i.e. totient(n)). Since this might be time-consuming (or practically impossible), the user can "help the command" by supplying such a factorization as the second parameter in the notation of ifactors:

```
zn_primroot(n, factorization)
```

Example

```
p:2^142 + 217;
ifs:ifactors(totient(p));
g:zn_primroot(p, ifs);
```

Our public key is the pair $(n, x)$ where $x$ is a primitive root modulo $n$; there is no private key. When A and B wish to communicate, they both select random numbers $a$ and $b$ modulo $n$.

A sends B the message $x^{a}(\bmod n)$, and B sends A the message $x^{b}$ $(\bmod n)$. When A receives this, he raises it to the $a^{\text {th }}$ power modulo $n$, and B raises A's message to the $b^{\text {th }}$ power modulo $n$.

As the end of this exchange, both A and B have a shared secret

$$
x^{a \cdot b} \quad(\bmod n)
$$

that no one else knows. This secret can be used as a key for a more conventional (agreed-upon) cryptosystem ${ }^{7}$ that is used for further communication.

Its security depends on computing $a(\bmod n)$, given $n, x$, and $x^{a}(\bmod n)-$ the so-called discrete logarithm problem: In a manner of speaking $a=\log _{x} x^{a}$, the logarithm of $x^{a}$ - or it would be if computations were done over $\mathbb{R}$ rather than $\mathbb{Z}_{n}^{\times}$.

There are no known efficient algorithms for solving this other than raising $x$ to all possible powers and comparing the result with $x^{a}(\bmod n)$. Since $a$ might be a large number, this could be computationally expensive.

Compare this with the treatment of elliptic-curve cryptography in [42, section 6.2.2].

After all this, it's important to mention that Maxima has a discrete logarithm command

```
zn_log(a,g,n)
```

If g is a primitive root modulo n , this solves the congruence $g^{x} \equiv a$ $(\bmod n)$, if a solution exists.

[^6]
## ExERCISES.

1. Modify the key-exchange algorithm to give a shared secret to $m$ people, where $m>2$.
2. Implement electronic signatures using Diffie-Hellman-Merkle key exchange.

### 2.5. Continued fractions

Here's an example of a continued fraction:

$$
\sqrt{2}=1+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2+\frac{1}{2}}}}}}}}}}}
$$

Euler developed much of the theory of continued fractions, proving that

$$
\arctan (x)=\frac{x}{1+\frac{1^{2} x^{2}}{3-x^{2}+\frac{3^{2} x^{2}}{5-3 x^{2}+\ldots}}}
$$

for $|x| \leq 1$, where the general term is

$$
\frac{(2 k-1)^{2} x^{2}}{2 k+1-(2 k-1) x^{2}+\cdots}
$$

Setting $x=1$ gives a nice continued fraction for $\pi / 4$.
The standard form for continued fractions have numerators equal to 1 , and it can be proved that every continued fraction is equal to one in the standard form (see [33]).

In Maxima, continued fractions are represented as lists

$$
\sqrt{2}=[1,2,2,2,2, \ldots]
$$

The results of truncating a continued fraction at a point is called a convergent of the fraction. In the case of algebraic numbers like $\sqrt{2}$, the terms repeat indefinitely and Maxima usually simply lists the sequence that repeats, so we get

```
cf(sqrt(2))
[1,2]
```

The cf-command attempts to find a continued fraction form of its parameter. It can work with linear combinations of square roots of integers (which all produce repeating continued fractions) and floating point numbers:

```
cf(%pi);
cf: %pi is not a continued fraction./*error message!*/
f:cf(float(%pi));
[3,7,15,1,292,1,1,1,2,1,3,1,14]
```

The command cfdisrep displays a continued fraction in its normal mode

```
cfdisrep(f)
```

returns

$$
3+\frac{1}{7+\frac{1}{15+\frac{1}{1+\frac{1}{292+\frac{1}{1+\frac{1}{1+\frac{1}{1+\frac{1}{2+\frac{1}{1+\frac{1}{3+\frac{1}{1+\frac{1}{14}}}}}}}}}}} .}
$$

The reader might wonder why we're interested in continued fractions (aside from the intriguing display they form on a printed page!). The answer is that their convergents (i.e. the results of truncating them after some finite point on) are rational numbers that converge to a real number faster than any other known representation - if the continued fraction is in standard form.

For instance, the command

```
cf(sqrt(2))
```

returns
[1,2]
which is not the answer ${ }^{8}$ ! The square root of 2 is the infinite periodic continued fraction
[1,2,2,2,2,2,2, ,..]
where the first term is the only one that isn't repeated. In mathematical notation, the nonperiodic portion is usually distinguished via a semicolon:
[1;2,2,2,2,2,2, ,..]
Maxima doesn't do this, which might be confusing if one doesn't know that $\sqrt{2}$ is irrational from the outset.

The parameter cflength determines the number of periods of a periodic continued fraction that will be displayed. The default is 1 . The author recommends setting this to something $>1$ !

In theory, then, if we want to build a computer that works with real numbers, we should store them as continued fractions. Unfortunately, performing basic arithmetic with continued fractions is difficult.
${ }^{8}$ It is a rational number!

There's a lengthy theory of continued fractions and how they can be used to prove numbers are irrational or transcendental. Again, see [33].

## CHAPTER 3

## Basic algebra and calculus

"L'algèbre n'est qu'une géométrie écrite; la géométrie n'est qu'une algèbre figurée." (Algebra is merely geometry in words; geometry is merely algebra in pictures)

- Sophie Germain, [18]

We can type $\mathrm{z}:(\mathrm{a}+\mathrm{b})^{\wedge} 5$. Try typing $\operatorname{expand}(\mathrm{z})$ to eliminate the parentheses and multiply out $a+b$ five times. The result is

$$
b^{5}+5 a b^{4}+10 a^{2} b^{3}+10 a^{3} b^{2}+5 a^{4} b+a^{5}
$$

Maxima can also factor algebraic expressions: type $z: a^{\wedge} 10+b^{\wedge} 10$ and Cell $\triangleright$ Evaluate Cell(s), then factor $(z)$ and Cell $\triangleright$ Evaluate Cell(s) to get

$$
\left(a^{8}-a^{6} b^{2}+a^{4} b^{4}-a^{2} b^{6}+b^{8}\right)\left(a^{2}+b^{2}\right)
$$

In the above, the letter z is an expression, and we can plug values in for its variables. For instance, type $\mathrm{z}(\mathrm{a}=1)$ and Cell $\triangleright$ Evaluate Cell(s) to get

$$
\left(b^{\wedge} 8-b^{\wedge} 6+b^{\wedge} 4-b^{\wedge} 2+1\right) *\left(b^{\wedge} 2+1\right)
$$

Maxima can solve equations with the solve command. Typing

```
solve(a* ( ^ 2+b*x+c=0,x)
```

solves for x and reproduces the familiar quadratic formula

$$
\left[x=-\frac{\sqrt{b^{2}-4 a c}+b}{2 a}, x=\frac{\sqrt{b^{2}-4 a c}-b}{2 a}\right]
$$

If we type
solve ( $\left.a * x^{\wedge} 3+b * x^{\wedge} 2+c * x+d=0, x\right)$
we get Tartaglia's formula for the roots of a cubic equation in figure 3.0.1 on the following page.

$$
\begin{aligned}
& {[x=} \\
& \left(\frac{-1}{2}-\frac{\sqrt{3} i}{2}\right)\left(\frac{\sqrt{27 a^{2} d^{2}+\left(4 b^{3}-18 a b c\right) d+4 a c^{3}-b^{2} c^{2}}}{23^{\frac{3}{2}} a^{2}}+\frac{\frac{b c}{a a}-\frac{3 d}{a}}{6}+\frac{(-1) b^{3}}{27 a^{3}}\right)^{\frac{1}{3}} \\
& \left.-\frac{\left(\frac{\sqrt{3} i}{2}+\frac{-1}{2}\right)\left(\frac{(-1) b^{2}}{9 a^{2}}+\frac{c}{3 a}\right)}{\left(\frac{\sqrt{27 a^{2} d^{2}+\left(4 b^{3}-18 a b c\right) d+4 a c^{3}-b^{2} c^{2}}}{23^{\frac{3}{2}} a^{2}}+\frac{b c}{a a}-\frac{3 d}{6}\right.}+\frac{(-1) b^{3}}{27 a^{3}}\right)^{\frac{1}{3}}+\frac{(-1) b}{3 a}, \\
& x=\left(\frac{\sqrt{3} i}{2}+\frac{-1}{2}\right)\left(\frac{\sqrt{27 a^{2} d^{2}+\left(4 b^{3}-18 a b c\right) d+4 a c^{3}-b^{2} c^{2}}}{23^{\frac{3}{2}} a^{2}}+\frac{\frac{b c}{a a}-\frac{3 d}{a}}{6}+\frac{(-1) b^{3}}{27 a^{3}}\right)^{\frac{1}{3}} \\
& -\frac{\left(\frac{-1}{2}-\frac{\sqrt{3} i}{2}\right)\left(\frac{(-1) b^{2}}{9 a^{2}}+\frac{c}{3 a}\right)}{\left(\frac{\sqrt{27 a^{2} d^{2}+\left(4 b^{3}-18 a b c\right) d+4 a c^{3}-b^{2} c^{2}}}{23^{\frac{3}{2}} a^{2}}+\frac{\frac{b c}{a a}-\frac{3 d}{a}}{6}+\frac{(-1) b^{3}}{27 a^{3}}\right)^{\frac{1}{3}}}+\frac{(-1) b}{3 a}, \\
& x=\left(\frac{\sqrt{27 a^{2} d^{2}+\left(4 b^{3}-18 a b c\right) d+4 a c^{3}-b^{2} c^{2}}}{23^{\frac{3}{2}} a^{2}}+\frac{\frac{b c}{a a}-\frac{3 d}{a}}{6}+\frac{(-1) b^{3}}{27 a^{3}}\right)^{\frac{1}{3}} \\
& \left.-\frac{\frac{(-1) b^{2}}{9 a^{2}}+\frac{c}{3 a}}{\left(\frac{\sqrt{27 a^{2} d^{2}+\left(4 b^{3}-18 a b c\right) d+4 a c^{3}-b^{2} c^{2}}}{23 \frac{3}{2} a^{2}}+\frac{\frac{b c}{a a}-\frac{3 d}{a}}{6}+\frac{(-1) b^{3}}{27 a^{3}}\right)^{\frac{1}{3}}}+\frac{(-1) b}{3 a}\right]
\end{aligned}
$$

Figure 3.0.1. Roots of a cubic equation

Niccolò Fontana Tartaglia (1499/1500 - 1557) was a mathematician, architect, surveyor, and bookkeeper in the then-Republic of Venice (now part of Italy). Tartaglia was the first to apply mathematics to computing the trajectories of cannonballs, known as ballistics, in his Nova Scientia, "A New Science."

He outlined his formula for the roots of a cubic polynomial in a poem based on Dante's Inferno.
Tartaglia had a tragic life. As a child, he was one of the few survivors of the massacre of the population of Brescia by French troops in the War of the League of Cambrai. His wounds made speech difficult or impossible, prompting the nickname Tartaglia ("stammerer").

We can also do this for a fourth degree polynomial, resulting in a much more complex formula. Something interesting happens if we go to the fifth degree. Maxima gives back the same polynomial we input. This is because no general formula exists for the roots of a polynomial of degree 5 or higher. See [40, chapter 8] for a proof of this.

To some extent, we can find approximate roots of polynomials (and other functions) numerically. Numeric methods have difficulty computing complex roots, and can fail in many cases. The advantage of the formulas is that they give exact answers (and they always work).

Suppose we have a polynomial $x^{4}+2 x^{3}-3 x+5$. Since it's fourthdegree, a formula exists for computing its roots exactly. Note that the messy
equation in figure 3.0.1 on the preceding page is enclosed in square brackets. This means it is a Maxima-list. We access members of a list via square brackets and an integer, starting from 1. If we type

```
roots: solve( }\mp@subsup{x}{}{\wedge}4+2*\mp@subsup{x}{}{\wedge}3-3*x+5=0,x
```

the 4 roots are roots [1], roots [2], roots[3], and roots [4].
Typing roots[1] and CelløEvaluate Cell(s) gives

If we apply the bfloat-command or menu-item Numeric $\triangleright$ To Bigfloat to the expression, we get the same expression, with decimal numbers instead of exact integers! This is a complex number, so we can apply the rectform-command or menu-item Simplify $\triangleright$ Complex Simplification $\triangleright$ Convert to Rectform to try to put it into standard complex notation. This gives us

$$
x=-\frac{1.603712691810368 b 0 \% i}{\sqrt{2}}-\frac{1.814527633159785 b 0}{\sqrt{2}}-5.0 b-1
$$

Applying the bfloat-command or menu-item Numeric $\triangleright$ To Bigfloat to this gives

$$
\begin{equation*}
x=-1.133996119454043 b 0 \% i-1.78306479405766 b 0 \tag{3.0.1}
\end{equation*}
$$

How do we check this? We use the subst-command or select Simplify $\triangleright$ Substitute. The command's format is

```
subst(new_value,old_variable,expression)
```

and it gives

$$
\begin{aligned}
& (-1.133996119454043 b 0 \% i-1.78306479405766 b 0)^{4} \\
& \quad+2.0 b 0(-1.133996119454043 b 0 \% i-1.78306479405766 b 0)^{3} \\
& \quad-3.0 b 0(-1.133996119454043 b 0 \% i-1.78306479405766 b 0)+5.0 b 0
\end{aligned}
$$

which is not particularly enlightening. How do we get Maxima to multiply out the parenthesized expressions? We use the expand-command or menuitem Simplify $\triangleright$ Expand Expression to get

$$
6.661338147750939 b-16 \% i+4.662936703425657 b-15
$$

which is very close to 0 . This shows that equation 3.0.1 on the preceding page defines an (approximate) root of $x^{4}+2 x^{3}-3 x+5$.

The next root, roots [2], turns out to be its complex conjugate

$$
x=1.133996119454043 b 0 \% i-1.78306479405766 b 0
$$

roots[3] and roots[4] also turn out to be a complex conjugate pair.
If we try this with a fifth-degree polynomial

```
solve( }\mp@subsup{x}{}{\wedge}5+2*x-5=0,x)
```

we get

$$
\left[0=x^{5}+2 x-5\right]
$$

which simply says that the roots of this polynomial are the roots - i.e., Maxima cannot find exact roots. In this case, we can ask Maxima to use a $n u$ meric algorithm via
allroots ( $x^{\wedge} 5+2 * x-5$ );
to get
(3.0.2)

$$
\begin{gathered}
x=1.208917813386895, x=0.9409544200647337 \% i-1.167042002184507, \\
x=-0.9409544200647337 \% i-1.167042002184507, \\
x=1.234436184384532 \% i+0.5625830954910601, \\
x=0.5625830954910601-1.234436184384532 \% i
\end{gathered}
$$

In some cases, numeric algorithms do not converge.

## EXERCISES.

1. Suppose we only want a list of the roots of a polynomial rather than a list of equations like $x=$ root. Hint: use the rhs and map commands (look them up in the index or appendix $E$ on page 239).

### 3.1. Functions and programming

We have seen that identifiers like ' $z$ ', ' $a$ ', or ' $b$ ' can represent variables or expressions. They can also equal functions: type $f(x):=x^{\wedge} 2-3 * x+3$ and Cell $\triangleright$ Evaluate Cell(s) to define the identifier f to be a function. Note that

Figure 3.1.1. Simple plot
:= is used to define a function. We can also define "anonymous" functions using the lambda-command:
lambda ( $\mathrm{x}, \mathrm{y}], \mathrm{x} * \mathrm{y}$ )
Having defined a function, we can plot it with the command $\operatorname{plot2d}(f,[x, 0,3])$ to get figure 3.1.1

Standard form of this command:

```
plot2d(function /*or list*/ [f1,f2,...,fn],
[x,low_x,high_x]
/*optional:*/ ,[y,low_y,high_y]
    )
```

The list of functions allows you to plot multiple functions in a single plot. Note that text between /* and */ is regarded as a comment and is treated as white space by Maxima.

We can plot lambda-functions in a command
plot2d ([lambda ([x], $\left.x^{\wedge} 2\right)$, lambda ([x], $\left.x^{\wedge} 3\right)$, lambda ([x], $x^{\wedge} 7$ )],[x,0,1])
to get figure 3.1.2 on the next page.
Now that we have functions, we can also do calculus. Maxima has a derivative-command that does what its name implies. Its format is

```
derivative(expression, variable);
```

An alternate way computing derivatives uses the diff-command
diff(expression, variable);
which also allows for multiple derivatives

```
diff(expression, variable,number);
```

So typing

Figure 3.1.2. Lambda plots
diff( $\left.x^{\wedge} 2, x, 2\right)$;
gives 2.
Typing derivative $\left(x^{\wedge} x, x\right)$; gives

$$
x^{x}(\log (x)+1)
$$

If the expression has several variables, this becomes the partial derivative with respect to the variable listed ${ }^{1}$. For instance, derivative $\left(x^{\wedge}(x * y), x\right)$; and hitting Cell $\triangleright$ Evaluate Cell(s) gives

$$
x^{x y}(\log (x) y+y)
$$

and derivative $\left(\mathrm{x}^{\wedge}(\mathrm{x} * \mathrm{y}), \mathrm{y}\right)$; and hitting Cell $\triangleright$ Evaluate Cell(s) gives

$$
x^{x y+1} \log (x)
$$

Since we can compute derivatives, we can compute Taylor series, using the taylor-command ${ }^{2}$

```
taylor(function,variable, center,highest_power);
```

So
taylor ( $\sin (x), x, 0,10)$;
gives

$$
x-\frac{x^{3}}{6}+\frac{x^{5}}{120}-\frac{x^{7}}{5040}+\frac{x^{9}}{362880}+\ldots
$$

There is the closely related powerseries-command that attempts to compute a formula for the general coefficient. Its general form is

```
powerseries(function, variable,center);
```

For example
powerseries $(\sin (x), x, 0)$;
/* Note that the number of terms is not specified*/

[^7]gives
$$
\sum_{i 1=0}^{\infty} \frac{(-1)^{i 1} x^{2 i 1+1}}{(2 i 1+1)!}
$$

In cases where the powerseries-command "doesn't know" a formula for the general term (for example, $\sin (\sin (x))$ ), it repeats the input. The taylorcommand just computes derivatives and grinds out the taylor series to the required precision:

```
taylor(sin(sin(x)),x,0,10);
```

gives

$$
x-\frac{x^{3}}{3}+\frac{x^{5}}{10}-\frac{8 x^{7}}{315}+\frac{13 x^{9}}{2520}+\cdots
$$

Returning to $f(x):=x^{\wedge} 2-3 * x+3$, typing integrate $(f(x), x)$ gives

$$
\frac{x^{3}}{3}-\frac{3 x^{2}}{2}+3 x
$$

For definite integrals, we give the limits of integration: integrate $(f(x), x, 0,2)$; to get $\frac{8}{3}$. The general form of this command is

```
integrate(expression, variable)
```

with optional limits of integration. As with differentiation, the variable listed in the command is regarded as the only variable; the others are treated as constants. So

```
integrate( }\textrm{x}*\textrm{y}*\textrm{z},\textrm{y}
```

results in

$$
\frac{x y^{2} z}{2}
$$

The integrate()-command "knows" all the rules of integration taught in a calculus course (or in a table of integrals at the back of a textbook). For instance, if you type integrate $\left(1 /\left(1+x^{\wedge} 5\right), x\right)$, Maxima comes back with

$$
\begin{gathered}
\frac{\sqrt{5}(\sqrt{5}+1) \arctan \left(\frac{4 x+\sqrt{5}-1}{\sqrt{2 \sqrt{5}+10}}\right)}{5 \sqrt{2 \sqrt{5}+10}}+\frac{\sqrt{5}(\sqrt{5}-1) \arctan \left(\frac{4 x-\sqrt{5}-1}{\sqrt{-2 \sqrt{5}+10}}\right)}{5 \sqrt{-2 \sqrt{5}+10}} \\
-\frac{(\sqrt{5}+3) \log \left(2 x^{2}-x(\sqrt{5}+1)+2\right)}{10(\sqrt{5}+1)}-\frac{(\sqrt{5}-3) \log \left(2 x^{2}+x(\sqrt{5}-1)+2\right)}{10(\sqrt{5}-1)} \\
+\frac{1}{5} \log (x+1)
\end{gathered}
$$

This is clearly correct © !
In some cases, Maxima will simply return one's input. For instance, typing integrate $\left(x^{\wedge} x, x\right)$ gives

$$
\int x^{x} d x
$$

| $=$ | equality |
| :---: | :---: |
| $>$ | left side greater than right |
| $<$ | right side greater than left |
| $<=$ | less than or equal |
| $>=$ | greater than or equal |
| $\#$ | not equal |

Table 3.1.1. Maxima relational operators
which says "the integral is the integral". This is Maxima's way of saying it doesn't "know" how to get a more concrete formula for the integral of $x^{x}$.

If we type integrate $(x * \log (x), x, a, b)$;, Maxima asks us whether $1<$ $a$ and later, whether $a<b$. We can answer these questions beforehand via the assume-command:

```
assume (x>1)
assume(b>a)
```

type this prior to doing the integration, and Maxima won't ask questions.
Maxima has a complete programming language built into it for defining more complex functions. Suppose we want to define a function as follows:

$$
f(x)= \begin{cases}0 & x<-1  \tag{3.1.1}\\ 1 & -1 \leq x<0 \\ x^{2} & 0 \leq x \leq 1 \\ 0 & x>1\end{cases}
$$

To implement this function, we need if-statements and relational operators - see table 3.1.1. We could implement it as a complex nested if-statement

```
f(x):= if (x<-1) then 0
    else if ( }x<0\mathrm{ ) then 1
    else if ( }x<=1\mathrm{ ) then }\mp@subsup{x}{}{\wedge}
    else 0;
```

Maxima allows you to remove the space between else and if to form an elseif-command that does the same thing.

Maxima has a block-statement that can make it easier to define complex logical and other types of programs. Its general format given in figure 3.1.3.

```
block ([local_variables or empty list],
    statement1,
    statement2,
    value);
```

FIGURE 3.1.3. the block command

```
x:2;
block ([x:0,y,z], /*a local variable named x*/
    x:3,
    1);
/* x is still equal to 2 */
```

Figure 3.1.4. Local variables in a block-command

```
f(x) := block ([], /* no local variables */
    if(x<-1) then return (0),
    if(x<0) then return (1),
    if (x<=1) then return ( }\mp@subsup{x}{}{\wedge}2)\mathrm{ ,
    0); /*default final value */
```

FIGURE 3.1.5. $\quad f(x)$ written using a block-command

The value at the end is the result of the block-command executing. The local variables are created inside the block and never conflict with variables of the same name outside of it. Figure 3.1.4 illustrates this. The list of local variables can also (optionally) assign initial values to them.

If there are no local variables, the block-command still requires an empty list. Another way to exit a block is with the return-command. It exits the block with whatever value (enclosed in parentheses) it has as its parameter.

To summarize:
A block is the word block followed by a comma-separated sequence in parentheses
(1) The first element is a list of local variables or an empty list.
(2) The remaining entries (before the last one) are expressions.
(3) The last entry is a (numeric or symbolic) value.
(4) block statements can be nested to any depth.

One exits the block by either
(1) dropping through the last entry, or
(2) a return statement

So our discontinuous function in equation 3.1.1 on the preceding page could be coded as in figure 3.1.5.

Unfortunately, the derivative and integrate commands do not understand the logic of these little programs and we have to use a bit of ingenuity to compute them. For instance, to compute

$$
\int_{-\infty}^{\infty} f(x) d x
$$

we have to rewrite it as

$$
\begin{equation*}
\int_{-\infty}^{\infty} f(x) d x=\int_{-1}^{0} 1 d x+\int_{0}^{1} x^{2} d x=\frac{4}{3} \tag{3.1.2}
\end{equation*}
$$

Figure 3.1.6. False plot of $f(x)$

Plotting functions defined by programs also presents some special considerations. Maxima first tries to evaluate the function and then sends it to the plotting routines. For instance,
$\operatorname{plot} 2 d(f(x),[x,-5,5])$
produces a very uninteresting result: figure 3.1.6, where $f(x)$ appears to be identically 0 . This is because x starts out as $<-1$ and the first if statement is activated.

Oddly enough, we must suppress this initial evaluation of $f(x)$ via the quote-command which sends the literal function-code to the plotting routines,
plot2d('f(x),[x,-5,5])
to produce figure 3.1.7 on the facing page. Note that only a single quote is required.

It is somewhat difficult to see the behavior of this function from this particular plot. The plotting routines only use the minimum range of $y$ values necessary to represent the plot. It is better if we extend the range of $y$-values and restrict the $x$-values somewhat. Doing
plot2d('f(x),[x,-2,2],[y,-.5,1.5])
gives figure 3.1.8 on the next page
The programming language built into Maxima has many standard features that we will introduce as needed.

In many cases, it's difficult to analytically integrate a function and we have to resort to numerical methods. Calculus classes cover many methods for doing this, like Euler's Method, the Trapezoid Rule, and Simpson's Rule. One of the main Maxima commands for numeric integration is the quad_qag-command ${ }^{3}$. Its general format is

[^8]

Figure 3.1.7. First plot of $f(x)$

Figure 3.1.8. $\quad$ Better plot of $f(x)$
quad_qag(expression, variable, low,high, algorithm)
where algorithm is an integer from 1 to 6 . The result is a list of four elements

```
[estimated integral,
estimated error,
number of iterations,
error code]
```

If we compute

$$
\int_{.01}^{1} \sin \left(\frac{1}{x}\right) d x
$$

via
integrate $(\sin (1 / x), x, .01,1)$;
we get

$$
\begin{array}{r}
\frac{2 \sin (1)+\text { gamma_incomplete }(0, i)+\text { gamma_incomplete }(0,-i)}{2} \\
-0.5 \text { gamma_incomplete }(0,100 i)-0.5 \text { gamma_incomplete }(0,-100 i) \\
+0.005063656411097588
\end{array}
$$

After typing bfloat and expand, we get

$$
5.039818931754155 b-1
$$

which we will regard as the (semi-)exact value. The numerical methods produce results close to this:
quad_qag $(\sin (1 / x), x, .01,1,1)$;
produces

$$
\left[0.5039818931754158,2.307129694260507 * 10^{-9}, 615,0\right]
$$

Clearly, these numeric methods can produce very accurate estimates of definite integrals. Algorithm 6 gives a slightly more accurate estimate but the difference is not significant.

It is interesting that these numeric algorithms can handle functions defined like $f(x)$ defined in figure 3.1.5 on page 33. Typing

```
quad_qag(f(x),x,-5,5,1);
```

gives 0 . If we change this to
quad_qag('f(x), $x,-5,5,1$ );
we still get

$$
[0.0,0.0,15,0]
$$

But if we use another algorithm,
quad_qag('f(x), $x,-5,5,2$ );
we get

$$
\left[1.333333332896747,1.138680744111984 \cdot 10^{-8}, 2415,0\right]
$$

which is very close to the correct value of $4 / 3$. The other numeric algorithms give similar results.

### 3.2. Limits

Maxima can compute limits using L'Hôpital's rule and others. The limit-command has the format
limit (expression, variable, goal)
and can include an optional direction. For instance
limit ( $\left.\left(x^{\wedge} 3-x\right) /(x+1), x,-1\right)$
produces the result 2 . The command
limit $(x * \log (x), x, z e r o a)$
takes the limit of $x \log (x)$ as $x \rightarrow 0^{+}$, and is completely equivalent to the command ${ }^{4}$

```
limit(x*\operatorname{log}(x),x,0,plus)
```

### 3.3. Elimination theory

We consider the question
Given polynomials

$$
\begin{align*}
& f(x)=a_{n} x^{n}+\cdots+a_{0}  \tag{3.3.1}\\
& g(x)=b_{m} x^{m}+\cdots+b_{0} \tag{3.3.2}
\end{align*}
$$

when do they have a common root?
Sylvester studied this problem and solved it using a matrix from which he derived the resultant of the polynomials, $\operatorname{Res}(f, g, x)$.

PROPOSITION 3.3.1. The polynomials $f(x)$ and $g(x)$ have a common root if and only if $\operatorname{Res}(f, g, x)=0$.

Proof. See [40, section 6.2.4].

James Joseph Sylvester (1814-1897) was an English mathematician who made important contributions to matrix theory, invariant theory, number theory and other fields.

EXAMPLE. For instance, suppose we type

```
f:x^2-2*x+5;
g: x^3+x-3;
```

Then

```
resultant(f,g,x)
```

gives 169 , so these two polynomials have no common roots.
There are many interesting applications of the resultant. Suppose we are given parametric equations for a curve

$$
\begin{aligned}
x & =\frac{f_{1}(t)}{g_{1}(t)} \\
y & =\frac{f_{2}(t)}{g_{2}(t)}
\end{aligned}
$$

where $f_{i}$ and $g_{i}$ are polynomials, and want an implicit equation for that curve, i.e. one of the form

$$
F(x, y)=0
$$

[^9]This is equivalent to finding $x, y$ such that the polynomials

$$
\begin{aligned}
& f_{1}(t)-x g_{1}(t)=0 \\
& f_{2}(t)-y g_{2}(t)=0
\end{aligned}
$$

have a common root (in $t$ ). So the condition is

$$
\operatorname{Res}\left(f_{1}(t)-x g_{1}(t), f_{2}(t)-y g_{2}(t), t\right)=0
$$

This resultant will be a polynomial in $x$ and $y$. We have eliminated the variable $t$ and the study of such algebraic techniques is the basis of Elimination Theory.

## Example 3.3.2. Let

$$
\begin{aligned}
& x=t^{2} \\
& y=t^{2}(t+1)
\end{aligned}
$$

Then typing

```
resultant(t^2-x,t^2*(t+1)-y,t)
```

gives

$$
y^{2}-2 x y-x^{3}+x^{2}
$$

Issue the command

```
subst(t^2,x,y^2-2*x*y-x^3+x^2)
```

to get
$y^{\wedge} 2-2 * t^{\wedge} 2 * y-t^{\wedge} 6+t^{\wedge} 4$
and
subst $\left(t^{\wedge} 2 *(t+1), y, y^{\wedge} 2-2 * t^{\wedge} 2 * y-t^{\wedge} 6+t \wedge 4\right)$
to get
$\mathrm{t}^{\wedge} 4 *(\mathrm{t}+1)^{\wedge} 2-\mathrm{t}^{\wedge} 6+\mathrm{t} \wedge 4-2 * \mathrm{t}^{\wedge} 4 *(\mathrm{t}+1)$
Now, typing
expand (\%)
gives 0 . So

$$
-x^{3}+y^{2}-2 y x+x^{2}=0
$$

after plugging in the parametric equations for $x$ and $y$.
What is the connection with elimination theory? If we had the equations

$$
\begin{aligned}
& x-t^{2}=0 \\
& y-t^{2}(t+1)=0
\end{aligned}
$$

We could ask the question: "What conditions must $x$ and $y$, alone, satisfy for these two equations to be satisfied?" or "How can we eliminate $t$ from the original equations?"

Exercise 4 on the next page uses this to solve two simultaneous algebraic equations. This is the main application of the resultant. Solving more complex systems of algebraic equations requires a construction known as a Gröbner basis, which we will explore later.

## EXERCISES.

1. Compute an implicit equation for the curve defined parametrically by

$$
\begin{aligned}
& x=t /\left(1+t^{2}\right) \\
& y=t^{2} /(1-t)
\end{aligned}
$$

2. Compute an implicit equation for the curve

$$
\begin{aligned}
& x=t /\left(1-t^{2}\right) \\
& y=t /\left(1+t^{2}\right)
\end{aligned}
$$

3. Compute an implicit equation for the curve

$$
\begin{aligned}
& x=(1-t) /(1+t) \\
& y=t^{2} /\left(1+t^{2}\right)
\end{aligned}
$$

4. Solve the equations

$$
\begin{aligned}
x^{2}+y^{2} & =1 \\
x+2 y-y^{2} & =1
\end{aligned}
$$

by computing a suitable resultant to eliminate $y$.
5. Find implicit equations for $x, y$, and $z$ if

$$
\begin{aligned}
& x=s+t \\
& y=s^{2}-t^{2} \\
& z=2 s-3 t^{2}
\end{aligned}
$$

Hint: Compute resultants to eliminate $s$ from every pair of equations and then eliminate $t$ from the resultants.

## CHAPTER 4

## Differential Equations

> "Science is a differential equation. Religion is a boundary condition."
> - Alan Turing.

### 4.1. Introduction

Suppose we have a first-order differential equation

$$
\frac{d y}{d x}=f(x, y)
$$

At each point, the function $f(x, y)$ defines a direction, i.e. a slope. A solution to the differential equation is a curve through the points whose slope matches the direction-field defined by $f(x, y)$. Intuition tells us that a solution passes through each point where $f(x, y)$ is well-defined. Simply draw a curve in the direction the arrows point. Intuition also tells us that this solution will be unique: if you steer a car the same way two times in a row, you end up at the same destination. This is the Cauchy-Lipschitz Theorem - see [44].

For instance, the equation

$$
\begin{equation*}
\frac{d y}{d x}=x+y \tag{4.1.1}
\end{equation*}
$$

defines the direction-field in figure 4.1.1 on the following page, and a solution is the curve whose direction matches the arrows. We can see this direction-field by using the plotdf-command:

$$
\operatorname{plotd} f(x+y,[x,-2,2],[y,-2,2])
$$

One nice feature of the resulting plot is that clicking on the plot produces a solution-curve (computed numerically) to equation 4.1.1 that passes through the point you clicked.

If the variables in the plot are not $x$ and $y$, one must list them:

$$
\operatorname{plotd} f(u * v,[u, v],[u,-2,2],[v,-2,2])
$$

This is a very complex command with many options that can be accessed from a menu on the plot itself or in the command-line. Each option in the command-line is enclosed in a list with the name of the option and its value:
(1) [tstep,value] the size of the steps taken in approximating a solution to the differential equation. The default is .1.
(2) [nsteps,value] the number of steps taken to draw the solutioncurve. Default is 100 .

Figure 4.1.1. Direction-field defined by equation 4.1.1 on the preceding page
(3) [direction, option] defines the direction of the independent variable that will be followed to compute an integral curve. Possible values are forward, to make the independent variable increase nsteps times, with increments tstep, backward, to make the independent variable decrease, or both that will lead to an integral curve that extends nsteps forward, and nsteps backward. The keywords right and left can be used as synonyms for forward and backward. The default value is both.
(4) [tinitial,value] defines the initial value of variable $t$ used to compute integral curves. Since the differential equations are autonomous, that setting will only appear in the plot of the curves as functions of t . The default value is 0 . This refers to an alternate form of the plotdf-command in analyzing a system of two differential equations:

$$
\begin{align*}
& \frac{d x}{d t}=f(x, y) \\
& \frac{d y}{d t}=g(x, y) \tag{4.1.2}
\end{align*}
$$

and we plot the behavior of $x$ versus $y$ (the dependent variables could have other names, but the independent variable is always named t) in a command-line
plotdf([f,g],[x,y],[x,-2,2],[y,-2,2])
(5) [versus_t,number] is used to create a second plot window, with a plot of an integral curve, as two functions $x, y$, of the independent variable, $t$. If versus_t is given any value different from 0 , the second plot window will be displayed. The second plot window includes another menu, similar to the menu of the main plot window. The default value is 0 .
(6) [trajectory_at,coordinates] defines the coordinates xinitial and yinitial for the starting point of an integral curve. The option is empty by default. You can set this simply by clicking on the plot.
(7) ["parameter1=val1,parameter2=val2..." ] defines a list of parameters, and their numerical values, used in the definition of the differential equations. The name and values of the parameters must be given in a string with a comma-separated sequence of pairs name=value.
(8) [sliders, "par1=min:max,par2=min:max..."] defines a list of parameters that will be changed interactively using slider buttons, and the range of variation of those parameters. The names and ranges of the parameters must be given in a string with a commaseparated sequence of elements name=min:max.
(9) [xfun, "function1,function2,..."] defines a string with semi-colonseparated sequence of functions of $x$ to be displayed, on top of the direction field.
(10) $[x, m i n, m a x]$ sets up the minimum and maximum values shown on the horizontal axis. If the variable on the horizontal axis is not x , then this option should have the name of the variable on the horizontal axis. The default horizontal range is from -10 to 10 .
(11) $[y, \min , \max ]$ sets up the minimum and maximum values shown on the vertical axis. If the variable on the vertical axis is not $y$, then this option should have the name of the variable on the vertical axis. The default vertical range is from -10 to 10 .
Maxima "knows" the basic methods for symbolically solving first and second-order differential equations. One of the main commands for this is the ode2-command, which has the basic form
ode2 (equation, dependent-var, independent-var)

For example

$$
\text { ode2 }\left({ }^{\prime} \operatorname{diff}(y(x), x)=x+y(x), y(x), x\right)
$$

results in

$$
y(x)=\left((-x-1) * \% e^{-x}+\% c\right) * \% e^{x}
$$

where $\% \mathrm{c}$ is an arbitrary constant. We must quote the diff-command because we don't want it to compute the derivative; we just want to indicate that differentiation takes place. If we type

```
expand(%)
```

we get the simplified form

$$
y(x)=\% c \% e^{x}-x-1
$$

The ic1-command selects (by adjusting the arbitrary constant) the solution that passes through a given point.

Given

```
sol:ode2('diff(y(x),x)=x+y(x),y(x),x)
```

and
ic1 ( sol, $x=2, y(x)=3)$
we get

$$
\mathrm{y}(x)=\% e^{-2}\left((\mathrm{y}(2)+3) \% e^{x}-\% e^{2} x-\% e^{2}\right)
$$

and expand $(\%)$ gives

$$
\mathrm{y}(x)=\mathrm{y}(2) \% e^{x-2}+3 \% e^{x-2}-x-1
$$

The ode2-command also handles second-order differential equations. For instance
sol:ode2 ( $\left.\mathrm{x} *\left({ }^{\prime} \operatorname{diff}(\mathrm{y}, \mathrm{x}, 2)\right)-\mathrm{C}^{\prime} \operatorname{diff}(\mathrm{y}, \mathrm{x})+\mathrm{x}=0, \mathrm{y}, \mathrm{x}\right)$;
produces the output

$$
y=-\frac{2 x^{2} \log (x)-x^{2}}{4}+\% \mathrm{k} 2 x^{2}-\frac{\% \mathrm{k} 1}{2}
$$

where $\% \mathrm{k} 1$ and $\% \mathrm{k} 2$ are arbitrary constants ${ }^{1}$.
As with first order differential equations, there's a command to set the arbitrary constants to appropriate values to satisfy initial conditions: the ic2-command.

$$
\text { ic2 }(\text { sol , } x=1, y=2, \quad \text { 'diff }(y, x)=1) ;
$$

produces

$$
y=-\frac{2 x^{2} \log (x)-x^{2}}{4}+\frac{x^{2}}{2}+\frac{5}{4}
$$

This is a perfect opportunity to introduce the ratsimp-command which simplifies rational expressions ${ }^{2}$. Typing ratsimp(\%) gives

$$
y=-\frac{2 x^{2} \log (x)-3 x^{2}-5}{4}
$$

In cases where Maxima doesn't "know" how to solve a differential equation, it returns with False.

Another interesting "simplification" command is radcan.
EXAMPLE 4.1.1. The Logistics Equation. Imagine there is a population, $P$, and a disease is circulating through it. The function $y(t)$ is the number of people infected and, of course, $P-y(t)$ is the number uninfected. The probability of people getting infected is proportional to the product of these, so we get a differential equation

$$
\begin{equation*}
\frac{d y}{d t}=k y\left(1-\frac{y}{P}\right) \tag{4.1.3}
\end{equation*}
$$

We type
1sol:ode2('diff $(y, t)=k * y *(1-y / P), y, t)$

[^10]

Figure 4.1.2. The Logistic Curve
and get

$$
-\frac{\log (y-P)-\log (y)}{k}=t+\% c
$$

Now, we decide that the first case of this disease happened at time 0 and issue the command

```
ic1(lsol,t=0,y=1);
```

to get

$$
-\frac{\log (y-P)-\log (y)}{k}=\frac{k t-\log (1-P)}{k}
$$

which doesn't quite solve the problem. If we issue the logcontract-command, we get

$$
\frac{\log \left(\frac{y}{y-P}\right)}{k}=\frac{k t-\log (1-P)}{k}
$$

which is slightly more useful. At this point, we can type

```
solve(%,y);
```

to get

$$
\left[y=\frac{P \% e^{k t}}{\% e^{k t}+P-1}\right]
$$

If we set $P=100$ and $k=1$, we can plot this via

$$
\text { plot2d }\left(\left(100 * \% e^{\wedge} t\right) /\left(\% e^{\wedge} t+99\right),[t, 0,10]\right) ;
$$

to get the well-known Logistic Curve or the Sigmoid Curve in figure 4.1.2 Equation 4.1.3 on the facing page was first proposed by Pierre-François Verhulst in modeling population growth with limited resources. In this case, $P$ represents the carrying capacity of the environment. The logistic curve is also used to model bacterial growth.

Pierre-François Verhulst (1804-1849) was a Belgian mathematician from the University of Ghent. He is best known for the logistic growth model in his notable paper of 1845. His use of the term "logistic" was probably influenced by his association with the Belgian military (he briefly taught in their military academy). For the military, the word "logistics" represent supplies and shipping.

We also have the desolve-command for solving systems of linear ordinary differential equations. The general format is

```
desolve([list of equations],[list of functions])
```

EXAMPLE 4.1.2. Suppose we have equations

```
eqn_1: 'diff(f(x),x,2)=sin(x) +' 'diff(g(x),x);
eqn_2: 'diff(f(x),x) + x^2 - f(x) = 2*'diff(g(x),x,2);
```

We solve them by typing

```
desolve([eqn_1,eqn_2],[f(x),g(x)])
```

and get a huge expression. We can simplify this somewhat by giving initial conditions

```
atvalue('diff(f(x),x),x=0,a);
atvalue(f(x), x=0,1);
```

specifying that $f(0)=1$ and

$$
\left.\frac{d f}{d x}\right|_{x=0}=a
$$

and re-issue the desolve-command to get

$$
\begin{aligned}
f(x) & =-\frac{3 \sin (x)}{5}+\frac{\cos (x)}{5}+ \\
& \frac{\left(\frac{\left(4(2 a-2)-\frac{16}{5}\right) \sin \left(\frac{x}{2}\right)}{2}-\frac{8 \cos \left(\frac{x}{2}\right)}{5}\right) \% e^{\frac{x}{2}}}{2} \\
& -\frac{2 \% e^{-x}}{5}+x^{2}+2 x+2
\end{aligned}
$$

and

$$
\begin{aligned}
\mathrm{g}(x) & =-\frac{\sin (x)}{5}+\frac{2 \cos (x)}{5}+ \\
& \frac{\left(\frac{\left(\frac{2(10 a-18)}{5}+\frac{16}{5}\right) \sin \left(\frac{x}{2}\right)}{2}+\frac{(10 a-18) \cos \left(\frac{x}{2}\right)}{5}\right) \% e^{\frac{x}{2}}}{2} \\
& +\frac{2 \% e^{-x}}{5}+2 x-a+\mathrm{g}(0)+1
\end{aligned}
$$

Important note: In using desolve, functions must be written as such: in other words, one must write $f(x)$ rather than just $f$ !

Suppose we have a differential equation like

$$
\begin{equation*}
\frac{d y}{d x}=3 \sin (\sin (y)) \tag{4.1.4}
\end{equation*}
$$

This is highly nonlinear, and ode 2 comes back with

$$
\frac{\int \frac{1}{\sin (\sin (y))} d y}{3}=x+\% \mathrm{c}
$$

which isn't very helpful. Maxima's puny brain simply can't handle it. In this case, we are reduced to solving it numerically.

Euler proposed the first numeric algorithm for solving an equation like

$$
\frac{d y}{d x}=f(x, y)
$$

It involved replacing the derivative by finite differences:

$$
\begin{equation*}
\frac{\Delta y}{\Delta x}=f(x, y) \tag{4.1.5}
\end{equation*}
$$

so

$$
f\left(x_{i+1}\right)=f\left(x_{i}\right)+\left(x_{i+1}-x_{i}\right) \cdot f\left(x_{i}, y_{i}\right)
$$

This crude approximation becomes more accurate the smaller $x_{i+1}-x_{i}$ becomes. Maxima uses a similar but more sophisticated algorithm called the fourth-order Runge-Kutta algorithm.

Carl David Tolmé Runge (1856-1927) was a German mathematician, physicist, and spectroscopist.
He was co-developer and co-eponym of the Runge-Kutta method, in the field of what is today known as numerical analysis. In addition to pure mathematics, he did experimental work studying spectral lines of various elements (together with Heinrich Kayser), and was very interested in the application of this work to astronomical spectroscopy.

Martin Wilhelm Kutta (1867 - 1944) was a German mathematician. In 1901, he co-developed the Runge-Kutta method, used to solve ordinary differential equations numerically. He is also remembered for the Zhukovsky-Kutta aerofoil (used in modern airplanes), the Kutta-Zhukovsky theorem and the Kutta condition in aerodynamics.

Maxima implements this with the rk-command, which takes one of the following two forms:

```
rk(diff-equation,dependent-variable,initial-value
[independent-var,start,finish,delta])
```

Note: since the algorithm assumes that all equations are of the form

$$
\frac{d y}{d x}=f(x, y)
$$

you only list the ' $f(x, y)$ ' in the algorithm.
The smaller delta is, the more accurate the approximation.

Figure 4.1.3. Output of the Runge-Kutta algorithm

For equation 4.1.4 on the previous page, we could program this as

$$
\operatorname{rk}(3 * \sin (\sin (y)), y, 2,[x, 0,5, .01])
$$

The command comes back with a long list of the form
[ [x1, y1],[x2,y2],etc]
We can plot this using the 'discrete' option to the plot2d-command. This has the general form
plot2d([discrete,[[x1,y1],[x2,y2], etc.],[y,lowy,highy])
So we run

```
point_list:rk(3*sin(sin(y)),y,2,[x,0,5,.01])
```

and

```
plot2d([discrete, point_list],[y,0,5])
```

to get the plot in figure 4.1.3. One nice feature of the rk-command is that it can handle systems of differential equations. In this form, it is coded

```
rk([ode1,ode2,etc ,] ,[var1,var2,etc ,],
[init1,init2,etc.],[independent-var,low,high,delta])
```

We can solve the system

$$
\begin{align*}
& \frac{d x}{d t}=3 x-4 y  \tag{4.1.6}\\
& \frac{d y}{d t}=2 x+3 y
\end{align*}
$$

via
results: $\operatorname{rk}([3 * x-4 * y, 2 * x+3 * y],[x, y],[2,3],[t, 0,4, .01])$
The output (results) is a list of the form
[ [ t1 , x1, y1],[t2,x2,y2],etc.]
which must be reformatted (via the makelist-command) to suit the plot2dcommand:

Figure 4.1.4. Plot of two solutions

```
xgraph:makelist([p[1],p[2]],p,results)
```

and
ygraph: makelist ([p[1], p[3]], p, results)
Now we can plot both solutions via

```
plot2d([[discrete,xgraph],[discrete,ygraph]],
[y,-100,100]);
```

to get figure 4.1.4.

## EXERCISES

1. Solve equations 4.1.6 on the facing page exactly via the desolvecommand.
2. Convert the equation

$$
\frac{d y^{2}}{d x^{2}}-3\left(\frac{d y}{d x}\right)^{3}+2 y=0
$$

into a system of first-degree equations suitable for solving via the rk-command.
3. Plot a solution to the differential equation

$$
\frac{d y}{d x}=x-y^{2}
$$

with $y(-1)=3$ with a comparison plot of $\sqrt{x}$.
4. Plot solutions to the system of differential equations

$$
\begin{aligned}
& \frac{d z}{d x}=v \\
& \frac{d v}{d t}=-k z / m
\end{aligned}
$$

through the point $(z, v)=(6,0)$ with $k=2$ and a slider for varying $m$ from 1 to 5 .
5. Try simplifying the output of desolve in example 4.1.2 on page 46 using ratsimp. The result will look more complicated, showing that simplification of an expression is a complex question with no obvious solution. Can these expresssions be further simplified?

### 4.2. Into the wild

Consider a forest with two populations: rabbits and foxes. The rabbits live in a leporine paradise - with unlimited resources allowing them to breed with reckless abandon. At least it would be a paradise were it not for the voracious foxes. Encounters between rabbits and foxes end badly for the rabbits and well for the foxes. Rabbits are the foxes' only sources of food.

The chances of rabbits meeting foxes is proportional to the product of their populations. If $r(t)$ and $f(t)$ represent the rabbit and fox populations, respectively, we get the differential equations

$$
\begin{aligned}
& \frac{d r}{d t}=\alpha r-\beta r \cdot f \\
& \frac{d f}{d t}=-\gamma f+\delta r \cdot f
\end{aligned}
$$

where $\alpha, \beta, \gamma, \delta$ are nonnegative constants.
At first, we're tempted to use the desolve command to handle these equations. Unfortunately, the desolve-command only handles linear differential equations. The terms $r \cdot f$ make these equations very nonlinear.

> Alfred James Lotka $(1880-1949)$ was a US mathematician, physical chemist, and statistician, famous for his work in population dynamics and energetics. An American biophysicist, Lotka is best known for his proposal of the predator-prey model, developed simultaneously but independently by Vito Volterra. The Lotka-Volterra model is still the basis of many models used in the analysis of population dynamics in ecology.

Vito Volterra (1860-1940) was an Italian mathematician and physicist, known for his contributions to mathematical biology and integral equations, and being one of the founders of functional analysis.

We initially fall back on the trusty plotdf-command.

```
plotdf([a*r-b*r*f,-c*f+d*r*f], [r,f],
[parameters," a=.2,b=.2,c=.1,d=.2"],
[sliders," }\textrm{a}=.1:5,\textrm{b}=.1:5,\textrm{c}=.1:5,\textrm{d}=.1:5"]
```

To produce figure 4.2.1 on the facing page. The fact that there is a closed curve shows that there is a periodic phenomena involved. It is interesting to move the sliders and see where the plot goes.

Figure 4.2.1. Plot of rabbits versus foxes

Figure 4.2.2. Rabbits and foxes

To see actual plots of foxes and rabbits, re-run the command with the versus_t option set to something nonzero:

```
plotdf([a*r-b*r*f,-c*f+d*r*f], [r,f],
[parameters," a =.2,b=.2,c=.1,d=.2"],
[sliders," a =.1:5,b=.1:5,c=.1:5,d=.1:5"],
[versus_t,1])
```

We get a second plot window with actual solutions for rabbits and foxes in figure 4.2.2.

Again, moving the sliders around varies the behavior of the plots. They show that, when the fox-population is low, the rabbits freely multiply. Then the foxes have an abundant food-source and they multiply, causing the rabbit-population to plunge. This cycle repeats, with slight variations. This phenomena has been observed in the wild - see [37].

To get a more accurate (and quantitative solution) we can use the rkcommand:

```
populations:rk([r-.01*r*f,-f+.01*r*f],[r,f],
[1000,10],[t,0,10,.01]);
```

If you examine the numbers coming from this simulation, you will notice fractional rabbits and foxes - the famous atto-fox problem - where an attofox is $10^{-18}$ of a fox ${ }^{3}$. See [29].

## ExERCISES.

1. If a cannon is inclined $30^{\circ}$ and fired with a muzzle-velocity of 1000 meters per second, what is the maximum altitude the shell will reach? Assume air-resistance is negligible and the acceleration of gravity is -9.8 $\mathrm{m} /$ second.
2. Same problem as the above with air-resistance given by

$$
\begin{equation*}
F=\frac{1}{2} C_{D} \rho A v^{2} \tag{4.2.1}
\end{equation*}
$$

where $C_{D}$ is a dimensionless constant (assume it is .47 ), $\rho$ is the density of the air (assume it is $1.225 \mathrm{~kg} / \mathrm{m}^{3}$ at sea-level and doesn't change with altitude), and $A$ is the cross-sectional area of the cannonball (assume it is . 2 square meters). Assume the cannonball weighs 4 kg .

### 4.3. The Heat Equation

Imagine a wire that is heated in some fashion. The flow and diffusion of heat through the wire is expressed by the one-dimensional heat equation

$$
\frac{1}{a^{2}} \frac{\partial^{2} \psi(x, t)}{\partial x^{2}}=\frac{\partial \psi(x, t)}{\partial t}
$$

where $\psi(x, t)$ is temperature, $x$ is distance, and $t$ is time. We will discuss its "meaning" later. In this equation, $a$ is a constant that represents how fast heat flows through the material in question; we will simplify matters by assuming it is 1 .

In his research on this equation, Fourier discovered that trigonometric polynomials play an important part. What is a trigonometric polynomial? For our purposes, it is a linear combination

$$
\begin{equation*}
f(x)=b_{0}+\sum_{j=1}^{k} a_{j} \sin (j x)+b_{j} \cos (j x) \tag{4.3.1}
\end{equation*}
$$

where the coefficients, $\left\{a_{i}, b_{i}\right\}$ are real numbers.

[^11]Jean-Baptiste Joseph Fourier (1768-1830) was a French mathematician and physicist born in Auxerre and best known for initiating the investigation of Fourier series, which eventually developed into Fourier analysis and harmonic analysis, and their applications to problems of heat transfer and vibrations. The Fourier transform and Fourier's law of conduction are also named in his honor. Fourier is also generally credited with discovering the greenhouse effect.

Suppose someone provides us with an unknown function, $g(x)$, (a "black box" that gives us a function-value when we supply a value for $x$ ) and whispers "This is a trigonometric polynomial". How are we to check this claim or compute its coefficients?

If we type
integrate $(\sin (n * x), x,-\% p i, \% p i)$
we get 0 . If we type
integrate $(\cos (n * x), x,-\% p i, \% p i)$
we get
$2 * \sin (\% \mathrm{pi} * \mathrm{n}) / \mathrm{n}$
Of course, this is for an arbitrary value of $n$ (like 2.7, for instance). If we insist that $n$ is an integer, via the declare-command

```
declare(n,integer)
```

then
integrate $(\cos (n * x), x,-\% p i, \% p i)$
gives 0 , so that

$$
\int_{-\pi}^{\pi} \sin (n x) d x=\int_{-\pi}^{\pi} \cos (n x) d x=0
$$

for $n$ an integer. For $f(x)$ in equation 4.3.1 on the facing page, it follows that

$$
\int_{-\pi}^{\pi} f(x) d x=b_{0} \int_{-\pi}^{\pi} d x=2 \pi b_{0}
$$

so

$$
\begin{equation*}
b_{0}=\frac{1}{2 \pi} \int_{-\pi}^{\pi} f(x) d x \tag{4.3.2}
\end{equation*}
$$

Next, Fourier noted that

$$
\begin{equation*}
\int_{-\pi}^{\pi} \sin (n x) \cos (m x) d x=0 \tag{4.3.3}
\end{equation*}
$$

because this is an odd function ${ }^{4}$ integrated over a symmetric range. It follows that

$$
\begin{align*}
& \int_{\pi}^{\pi} f(x) \sin (n x) d x=a_{1} \int_{-\pi}^{\pi} \sin (x) \sin (n x) d x+  \tag{4.3.4}\\
& \cdots+a_{n} \int_{-\pi}^{\pi} \sin ^{2}(n x) d x+\cdots+a_{k} \int_{-\pi}^{\pi} \sin (n x) \sin (k x) d x \\
& \quad+0+\cdots+0
\end{align*}
$$

If we type

```
declare(m, integer);
integrate( }\operatorname{sin}(n*x)*\operatorname{sin}(m*x),x,-%pi,%pi)
integrate ( cos(n*x)* cos(m*x),x,-%pi,%pi);
```

we learn that get

$$
\begin{align*}
& \int_{-\pi}^{\pi} \sin (n x) \sin (m x) d x=0  \tag{4.3.5}\\
& \int_{-\pi}^{\pi} \cos (n x) \cos (m x) d x=0 \tag{4.3.6}
\end{align*}
$$

if $n \neq m$.
Incidentally, the reader might wonder what difference there is between the assume-command on page 32 and the declare-command used here. The assume-command describes numeric relations (usually inequalities) that exist between numeric identifiers, and the declare-command describes properties identifiers have (they might not be numeric ones).

If we type
integrate $\left(\sin (n * x)^{\wedge} 2, x,-\% p i, \% p i\right)$
we learn that

$$
\begin{equation*}
\int_{-\pi}^{\pi} \sin (n x) \sin (n x) d x=\pi \tag{4.3.7}
\end{equation*}
$$

It follows that equation 4.3 .4 can be rewritten as

$$
\int_{\pi}^{\pi} f(x) \sin (n x) d x=a_{1} \cdot 0+\cdots+a_{n} \cdot \pi+\cdots+a_{k} \cdot 0
$$

from which we get

$$
\begin{equation*}
a_{n}=\frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin (n x) d x \tag{4.3.8}
\end{equation*}
$$

A similar line of reasoning shows that

$$
\begin{equation*}
b_{n}=\frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos (n x) d x \tag{4.3.9}
\end{equation*}
$$

So we have an answer to our question:
$g(x)$ is a trigonometric polynomial if only a finite number of the $a_{n}$ and $b_{n}$, computed using equations 4.3.8 and 4.3.9 are nonzero.

[^12]This would've ended matters if Fourier hadn't taken the next step: apply these equations to a function that is definitely not a trigonometric polynomial - for instance the bizarre function, $f(x)$, plotted in figure 3.1.8 on page 35! Recall that it is defined via

```
f(x) := block ([], /* no local variables */
    if(x<-1) then return (0),
    if (x<0) then return (1),
    if (x<=1) then return ( }\mp@subsup{x}{}{\wedge}2)\mathrm{ ,
    0);
```

We will define functions to compute the coefficients in equations 4.3.8 on the preceding page and 4.3 .9 on the facing page (following the example of equation 3.1.2 on page 33):

```
a(k):= (integrate(sin (k*x), x, -1,0)
+integrate(sin (k*x)*x^2,x,0,1))/% pi
```

If we type a(3), we get

$$
\frac{\frac{2 \sin (2)-\cos (2)}{4}+\frac{\cos (2)-1}{2}-\frac{1}{4}}{\pi}
$$

which is a bit awkward. This expression should be simplified or consolidated. If we type ratsimp(\%), we get

$$
\frac{2 \sin (2)+\cos (2)-3}{4 \pi}
$$

which is more compact. We incorporate this into our function for $a(k)$ :

```
a(k):= ratsimp((integrate(sin (k*x), x, -1,0)
+integrate(sin}(k*x)*x^2,x,0,1))/% pi
```

We also have a similar function to compute the cosine coefficients

```
b(k):= ratsimp((integrate (cos(k*x), x,-1,0)
+integrate ( cos(k*x)* (^^2,x,0,1))/% pi)
```

If we define b0 via equations 4.3.2 on page 53 and 3.1.2 on page 33,

```
b0:2/(3*% pi );
```

Now we write a function to add up terms of the trigonometric polynomials with these coefficients. There are several ways to do this. We'll start with the while-command with a general format

```
while condition do
```

while condition do
(
(
statement1,
statement1,
statement2,
statement2,
statementn
statementn
)

```
)
```

Figure 4.3.1. First three terms

To compute the sum of the first $n$ terms of our trigonometric polynomial, we code

```
first_n(n,x):= block (
    [sum:2/(3*%pi), k:1], /*local variables */
    while k<=n do
    (
    sum:sum+a(k)*\operatorname{sin}(k*x)+b(k)*\operatorname{cos}(k*x),
    k:k+1 /*increment the counter*/
    ),
    sum /* value returned */
    )
```

Now we can plot these trigonometric polynomials via

```
plot2d(first_n(3,x),[x,-3,3]);
```

to get figure 4.3.1. This doesn't tell us much but, like Fourier, we persist.
The sum of the first 10 terms gives figure 4.3 .2 on the next page, which is evocative. Plotting this with $\mathrm{f}(\mathrm{x})$ (or Wxmaxima-menu item

## Plot $\triangleright$ Plot 2d via

plot2d ([ first_n (10, x), 'f(x)],[x, 3,3$])$;
gives figure 4.3.3 on the facing page.
At this point, we go for broke and compare the first 100 terms via
plot2d ([first_n (100,x),'f(x)],[x,-3,3]);
to get figure 4.3.4 on the next page.
This is very evocative! Although $\mathrm{f}(\mathrm{x})$ is not a trigonometric polynomial, an infinite series of trigonometric terms seems to converge to it almost everywhere. This is the famous Fourier Series, and was the beginning of a whole field of mathematics called harmonic analysis. Notice that Fourier series are more "powerful" than, say, Taylor series. They can represent functions that are not necessarily differentiable or even continuous.

Figure 4.3.2. First 10 terms

Figure 4.3.3. Comparison of first 10 with $f(x)$

Figure 4.3.4. The first 100 terms

Since all the functions that go into a Fourier series are periodic, so is the series itself - see figure 4.3.5 on the following page.

Figure 4.3.5. Periodicity of a Fourier series
You may notice that the Fourier series "overshoots" and "undershoots" $\mathrm{f}(\mathrm{x})$ at the points where it is discontinuous. This is called Gibbs Phenomena and is illustrated by typing

```
plot2d([(first_n(100,x)-'f(x))^2],[x, - 3 , 3]);
```

to get figure 4.3.6 on the next page.
This does not go away as we add more terms; the peaks simply become narrower. This leads to the question:

In what sense does the Fourier series converge to $\mathrm{f}(\mathrm{x})$ ?
It turns out ${ }^{5}$ that if $f(x)$ is any function that can be integrated from $-\pi$ to $\pi$ and if $S_{n}(x)$ is the sum of the first $n$ terms of the Fourier series for $f(x)$, then

$$
\lim _{n \rightarrow \infty} \int_{-\pi}^{\pi}\left(S_{n}(x)-f(x)\right)^{2} d x=0
$$

In other words, the "space between the curves" of $f(x)$ and $S_{n}(x)$ goes to zero as $n$ goes to infinity. This is called $L_{2}$-convergence.

If the original function, $f(x)$, is continuous, the "space between the curves" of $f(x)$ and $S_{n}(x)$ going to zero intuitively implies that $S_{n}(x)$ converges to $f(x)$ for every value of $x$. This is called "pointwise convergence". See [38] for the details.

Claim: Virtually all readers of this book have used Fourier series.
How? The mp3 audio and the jpeg graphic formats are based on Fourier series. The jpeg format uses a two-dimensional version of it. The actual jpeg file is a string of Fourier coefficients. If the spikes in the Gibbs phenomena are narrower than a pixel, they have no effect on the final image. Something similar happens with mp3 files: the narrow spikes are high-frequency signals above the range of human hearing.

Maxima has a sum-command that would have eliminated the need for programming! Its general form is

```
sum(expression,index_variable,low,high );
```

[^13]

Figure 4.3.6. Gibbs Phenomena
and we could've written our function as

```
first_n(k,x):= 2/(3*%pi)
    +sum(a(j)* sin}(j*x)+b(j)*\operatorname{cos}(j*x),j,1,k)
```

### 4.4. Solution to the Heat Equation

At this point, the reader may wonder what all of this has to do with the Heat Equation. Recall that this is

$$
\frac{1}{a^{2}} \frac{\partial^{2} \psi(x, t)}{\partial x^{2}}=\frac{\partial \psi(x, t)}{\partial t}
$$

where we assume $a=1$. Fourier attempted a particularly simple solution in the form

$$
\psi(x, t)=u(x) \cdot v(t)
$$

Plugging this into the heat equation gives

$$
u^{\prime \prime} v=u v^{\prime}
$$

and we divide by $u v$ to get

$$
\frac{u^{\prime \prime}(x)}{u(x)}=\frac{v^{\prime}(t)}{v(t)}
$$

How can a function of one variable equal another of an unrelated variable? They both equal the same constant! So we have

$$
\frac{u^{\prime \prime}(x)}{u(x)}=\frac{v^{\prime}(t)}{v(t)}=c
$$

We have

$$
v^{\prime}(t)=c \cdot v(t)
$$

This is a simple differential equation, but we'll pretend we don't know the solution and use Maxima's ode2-command for solving ordinary differential equations of degree $\leq 2$. We'll start with the equation for $v(t)$ :
ode2 (' $\operatorname{diff}(\mathrm{v}, \mathrm{t})=\mathrm{c} * \mathrm{v}, \mathrm{v}, \mathrm{t})$;

Note that we must quote the diff-command because we don't want Maxima to try to compute a derivative; we just want to indicate that differentiation takes place.

We get

$$
v=\% c \% e^{c t}
$$

Here $\% \mathrm{c}$ is an arbitrary constant that is completely unrelated to c . If $c>0$, then, depending on the sign of $\% c$, we realize that the temperature becomes exponentially hot over time or exponentially cold.

This is a reminder that not all solutions of the heat equation physically occur!

To avoid being burned alive or frozen, we'll assume that $c<0$. This is traditionally written as

$$
\frac{u^{\prime \prime}(x)}{u(x)}=\frac{v^{\prime}(t)}{v(t)}=-\lambda
$$

where $\lambda>0$. The command

```
ode2('diff(v,t)=-lambda*v,v,t);
```

gives

$$
v=\% \mathrm{c} \% e^{-t \mathrm{lambda}}
$$

and the command
ode2('diff ( $u, x, 2$ ) $=-\operatorname{lambda} * u, u, x)$;
prompts the question of whether lambda is positive, negative or zero ${ }^{6}$. We answer 'positive' and get

$$
u=\% \mathrm{k} 1 \sin (x \sqrt{\text { lambda }})+\% \mathrm{k} 2 \cos (x \sqrt{\text { lambda }})
$$

where $\% \mathrm{k} 1$ and $\% \mathrm{k} 2$ are arbitrary constants. This gives a basic solution to the Heat Equation

$$
\psi(x, t)=(\% \mathrm{k} 1 \sin (x \sqrt{\text { lambda }})+\% \mathrm{k} 2 \cos (x \sqrt{\text { lambda }})) e^{- \text {lambda } t}
$$

Since the Heat Equation is linear, any linear combination of these basic solutions is also a solution.

At this point, we can set $\sqrt{\text { lambda }}=n$, an integer, and get a basic solution ${ }^{7}$

$$
\psi_{n}(x, t)=\left(\% \mathrm{k} 1_{n} \sin (n x)+\% \mathrm{k} 2_{n} \cos (n x)\right) e^{-n^{2} t}
$$

When $t=0$, this looks like a term of a trigonometric polynomial. We hit upon Fourier's solution to the Heat Equation:
(1) expand $\psi(x, 0)$ - the initial heat distribution - in a Fourier series,
(2) Multiply the $n^{\text {th }}$ term of this Fourier series by $e^{-n^{2} t}$. The resulting series defines $\psi(x, t)$ for $t \geq 0$.

[^14]

Figure 4.4.1. $\psi(x, .01)$

Figure 4.4.2. $\psi(x, .02)$

We can test this with our Fourier series for the discontinuous function $f(x)$ defined in equation 3.1.1 on page 32. We replace our command for partial sums of this with

```
psi_n(k,x,t):= 2/(3*%pi)
    +sum((a(j)*sin}(j*x
    +b(j)* cos(j*x))*%e^^(-j^2*t),j,1,k);
```

Figures 4.4.1 through 4.4.4 on the following page shows the time-evolution of $\psi$ : Heat flows from the hotter parts of the wire to the cooler ones. The "sharp" edges of the function become smooth, and it's clear that the heatdistribution becomes constant in the limit as $t \rightarrow \infty$.

### 4.5. Finer points of plotting

Maxima has no built-in plotting capabilities. It uses a very powerful independent software package called Gnuplot (automatically installed with Maxima). It also uses powerful plotting commands built into wxMaxima.

Figure 4.4.3. $\psi(x, .1)$

Figure 4.4.4. $\psi(x, 1)$

The commands plot2d (and plot3d!) only use the most basic features of Gnuplot. Since we have mentioned plot3d we may as well discuss it. It's general form is
plot3d(two-variable-expression,[x,low,high],[y,low,high ]);
For example
plot3d( $\left.\sin \left(x^{\wedge} 2+y^{\wedge} 3\right),[x,-2,2],[y,-2,2]\right)$;
produces figure 4.5.1 on the next page. The wxMaxima-menu Plot $\triangleright$ Plot 3d prompts you for all the necessary parameters. One nice thing about these plots is that you can rotate them with the mouse and see them from many different angles.

We can use the complete repertoire of Gnuplot commands to generate plots and diagrams. We would like to produce an animated image of the heat-flow in the wire. wxMaxima provides the with_slider_draw-command for for this. Its general format is given in figure 4.5.2 on the facing page. This command cycles through the list of values, setting the variable to each of them and runs the corresponding plot command.

We would like to plot the flow of heat in our heated wire. We use the command in figure 4.5.3 on the next page.

Figure 4.5.1. An example of plot3d

```
with_slider_draw(
    variable, /*variable to attach to the slider */
    list of values,
    plot-command, /*plot */
    plot-options /*optional graphic command */
    ); /* end of with_slider_draw-command */
```

FIGURE 4.5.2. with_slider_draw

```
with_slider_draw(
    t, /*variable to attach to the slider */
    makelist(j,j,0,100), /* list of integers */
    explicit(psi_n(100,x,.01*t),x,-%pi,%pi), /* plot */
    yrange= [0,1.2] /*optional graphic command */
    ); /* end of with_slider_draw-command */
```

Figure 4.5.3. Evolution of the heat equation
and wait a long time (Maxima is computing 101 plots of the $\psi$-function). Afterward, a window appears with a slider that animates the passage of time. The slider allows us to move time forward or backward and see how the process changed. One can right-click this plot to save it as an animated gif file.

In this context, explicit means plotting in the normal fashion that plot2d follows. The alternative is implicit, which plots points satisfying an equation
draw2d(implicit ( $\mathrm{x}^{\wedge} 4+\mathrm{y}^{\wedge} 4=1, \mathrm{x},-2,2, \mathrm{y},-2,2$ )
Before you click Cell $\triangleright$ Evaluate Cell(s), several explanations are in order. The second parameter of with_slider_draw must be a list, i.e. data like

$$
[1,2,3]
$$

This particular list would make for a pathetic animation, though - with only 3 frames! What we really need is a list of integers from 0 to 100 . Rather than typing out 101 numbers, we use the all-important makelist-command. It has several forms and can be used to create or modify lists.
(1) makelist(expression, variable, i0, i1) Makes a list of the expression with the variable set equal to integers from i0 to i1 (incremented by 1 each iteration). For instance
makelist(i, i, 1, 5)
produces the list

$$
[1,2,3,4,5]
$$

and

```
makelist( }\textrm{x}=\textrm{i}^^2, i, 1, 5)
```

produces the list

$$
[x=1, x=4, x=9, x=16, x=25]
$$

(2) makelist(expression, variable, list) Cycles through the elements of the list, setting the variable equal to each of them and creating a list of the expression evaluated at these values. For instance,

```
makelist(x=y, y, [a,b,[1, 2]])
```

produces

$$
[x=a, x=b, x=[1,2]]
$$

This form of the command can be used to reformat lists. Suppose

$$
a:[[1,2,3],[u, v, w],[i, j, k]]
$$

and we issue the command makelist $([p[2], p[1], p[2]], p, a)$. We get the result

$$
[[2,1,2],[v, u, v],[j, i, j]]
$$

Incidentally, these repeated computations (of $a(k)$ and $b(k)$ ) could benefit from a process called memoization. Since $a(k)$ and $b(k)$ only depend on $k$ it would be better if the functions stored their results and simply did a table-lookup whenever the same value of $k$ is used a second time. This is called memoizing the computations. Maxima makes this very simple:

```
a[k]:= ratsimp((integrate ( sin (k*x), x, -1,0)
    +integrate(sin (k*x)* *^2,x,0,1))/ % pi)
b[k]:= ratsimp((integrate ( cos (k*x), x, -1,0)
    +integrate ( cos(k*x)* x^2,x,0,1))/% pi)
```

All we have done here is replace $a(k)$ by $a[k]$ and $b(k)$ by $b[k]$. This is a signal to Maxima to store the computed values in an array. If an array-position already has a value in it, Maxima suppresses rerunning the function and simply returns the array-entry. This creates a problem if the program has bugs: it remembers the incorrect values. To erase these incorrect values, issue the kill-command: kill(a), kill(b).

We also have to rewrite the psi_n function slightly.

```
psi_n(k,x,t):= 2/(3*%pi)
    +sum((a[j]*sin (j*x) /*replaced a(j) by a[j] */
    +b[j]* cos(j *x))*% e^(-j^2*t),j,1,k);
```

Now you can click Cell $\triangleright$ Evaluate Cell(s)
For more information on plotting, see Appendix F on page 251.

### 4.6. The Wave Equation

4.6.1. Introduction. The one-dimensional wave equation looks like the heat equation with a slight difference

$$
\begin{equation*}
\frac{\partial^{2} \psi(x, t)}{\partial x^{2}}=\frac{1}{c^{2}} \frac{\partial^{2} \psi(x, t)}{\partial t^{2}} \tag{4.6.1}
\end{equation*}
$$

- the time derivative is second-order. One is to imagine a vibrating string, where the function $\psi(x, t)$ represents the displacement of the string at any given position and time.

The one-dimensional version was discovered by d'Alembert; the higher dimensional wave equation was discovered by Euler.

Jean-Baptiste le Rond d'Alembert (1717-1783) was a French mathematician, mechanician, physicist, philosopher, and music theorist. Until 1759 he was, together with Denis Diderot, a co-editor of the Encyclopédie. D'Alembert's formula for obtaining solutions to the wave equation is named after him. The wave equation is sometimes referred to as d'Alembert's equation, and the fundamental theorem of algebra is named after d'Alembert in French.

D'Alembert found a completely general solution to the one-dimensional wave equation:

$$
\psi(x, t)=f(x+c t)+g(x-c t)
$$

where $f$ and $g$ are arbitrary twice-differentiable functions ${ }^{8}$. As clever as this is, it is not clear how apply it to interesting situations. We will use a Fourier series approach.

As before, we assume $c=1$ and write

$$
\psi(x, t)=u(x) \cdot v(t)
$$

Plugging this into equation 4.6 .1 gives

$$
u^{\prime \prime}(x) \cdot v(t)=u(x) \cdot v^{\prime \prime}(t)
$$

or

$$
\frac{u^{\prime \prime}(x)}{u(x)}=\frac{v^{\prime \prime}(t)}{v(t)}=-\lambda
$$

and (via ode2, for instance) we get

$$
\begin{aligned}
u(x) & =\alpha \cos (x \sqrt{\lambda}+\beta \sin (x \sqrt{\lambda}) \\
v(t) & =\gamma \cos (t \sqrt{\lambda})+\delta \sin (t \sqrt{\lambda})
\end{aligned}
$$

where $\alpha, \beta, \gamma, \delta$ are arbitrary constants.
Now imagine that our string is fixed between supports at $x=0$ and $x=\pi$ so that $\psi(0, t)=0=\psi(\pi, t)$, for all values of $t$. The simplest way to ensure this is to set $\alpha=0$ and $\sin (\pi \sqrt{\lambda})=0$, or $\sqrt{\lambda}=n$, an integer.

We will consider two important special cases.

[^15]4.6.2. The plucked string. This is the kind of string found in a guitar or harpsichord.

In this case, the string is initially not in motion, so that

$$
\begin{equation*}
\frac{\partial \psi}{\partial t}=0 \tag{4.6.2}
\end{equation*}
$$

when $t=0$. Since a basic solution is

$$
\psi_{k}(x, t)=a_{k} \sin (k x)\left(b_{k} \sin (k t)+c_{k} \cos (k t)\right)
$$

the easiest way to ensure equation 4.6.2 is to set $b_{k}=0$ for all $k$. Our basic solutions reduce to

$$
\psi_{k}(x, t)=a_{k} \sin (k x) \cos (k t)
$$

and

$$
\psi_{k}(x, 0)=a_{k} \sin (k t)
$$

If the initial configuration of the string (the "plucking" function) is $f(x)$ for $0 \leq x \leq \pi$, we can define an odd function from $-\pi$ to $\pi$ :

$$
f_{1}(x)= \begin{cases}f(x) & \text { if } x \geq 0 \\ -f(-x) & \text { otherwise }\end{cases}
$$

and we can expand this in a Fourier series. Since $f_{1}(x)$ is odd, the cosine terms will all vanish:

$$
\begin{aligned}
b_{k} & =\frac{1}{\pi} \int_{-\pi}^{\pi} f_{1}(x) \cos (k x) d x \\
& =\frac{1}{\pi} \int_{-\pi}^{0} f_{1}(x) \cos (k x) d x+\frac{1}{\pi} \int_{0}^{\pi} f_{1}(x) \cos (k x) d x \\
& =-\frac{1}{\pi} \int_{0}^{\pi} f_{1}(x) \cos (k x) d x+\frac{1}{\pi} \int_{0}^{\pi} f_{1}(x) \cos (k x) d x \\
& =0
\end{aligned}
$$

The sine-terms tend to "double up"

$$
\begin{aligned}
a_{k} & =\frac{1}{\pi} \int_{-\pi}^{\pi} f_{1}(x) \sin (k x) d x \\
& =\frac{1}{\pi} \int_{-\pi}^{0} f_{1}(x) \sin (k x) d x+\frac{1}{\pi} \int_{0}^{\pi} f_{1}(x) \sin (k x) d x \\
& =\frac{1}{\pi} \int_{0}^{\pi} f_{1}(x) \sin (k x) d x+\frac{1}{\pi} \int_{0}^{\pi} f_{1}(x) \sin (k x) d x \\
& =\frac{2}{\pi} \int_{0}^{\pi} f_{1}(x) \sin (k x) d x
\end{aligned}
$$

So, we expand $f(x)$ in a Fourier series of sines, and the solution to the wave equation is

$$
\psi(x, t)=\sum_{k=1}^{\infty} a_{k} \sin (k x) \cos (k t)
$$

If we type

$$
\sin (n * x) * \cos (n * t)
$$

and issue the trigreduce-command (one of several commands for simplifying trigonometric expressions) we get

$$
\frac{\sin (n x+n t)}{2}+\frac{\sin (n x-n t)}{2}
$$

so

$$
\psi(x, t)=\frac{1}{2}\left(\sum_{k=1}^{\infty} a_{k} \sin (k x+k t)+\sum_{k=1}^{\infty} a_{k} \sin (k x-k t)\right)
$$

Now we ask ourselves "What is $\sum_{k=1}^{\infty} a_{k} \sin (k x)$ ?"
Well

$$
\sum_{k=1}^{\infty} a_{k} \sin (k x)= \begin{cases}f(x) & \text { if } 0 \leq x \leq \pi \\ -f(-x) & \text { if }-\pi \leq x \leq 0 \\ \text { Periodic with period } 2 \pi & \end{cases}
$$

So we get a closed form solution to the plucked wave equation:
Given a "plucking function"," $f(x)$, for $0 \leq x \leq \pi$ define

$$
\bar{f}(x)= \begin{cases}f(x) & \text { if } 0 \leq x \leq \pi \\ -f(-x) & \text { if }-\pi \leq x \leq 0 \\ \text { Periodic with period } 2 \pi & \end{cases}
$$

Then

$$
\psi(x, t)=\frac{1}{2}(\bar{f}(x+t)+\bar{f}(x-t))
$$

Let's compute!
We start with a "realistic" plucking function

$$
f(x)= \begin{cases}x / 2 & \text { for } 0 \leq x<1 \\ -\frac{x-\pi}{2 \pi-2} & \text { for } 1 \leq x \leq \pi\end{cases}
$$

This programs as

```
f (x):= block ([],
if (x<1) then return (x/2),
-(x-%pi)/(2*%pi-2)
)
```

and we can plot it via

```
plot2d('f(x),[x,0,%pi],[y,-1/2,1/2])
```

and we get figure 4.6.1 on the following page.
Now we define $\bar{f}(x)$ :

```
f_bar(x):= block ([],
if (x>%pi) then return (f_bar(x-2*%pi)),
if (x<=-%pi) then return (f_bar( }x+2*%pi))
if(x>=0) then return (f(x)),
-f(-x)
);
```

${ }^{9}$ I.e., shape of the string at time 0.

Figure 4.6.1. "Realistic" plucking function

FIGURE 4.6.2. The extended plucking function
and, to check this, we plot it
plot2d('f_bar(x),[x,-10,10],[y,-1/2,1/2])
and get figure 4.6.2.
psi_p (x, t):=(f_bar (x+t)+f_bar (x-t))/2
Which we can plot via

```
with_slider_draw(
    t, /*variable to attach to the slider */
    makelist(j, j,0,100), /* list of integers */
    explicit('psi_p(x,.1*t),x,0,%pi), /*plot */
    yrange= [-1/2,1/2] /*optional graphic command *<
    ); /* end of with_slider_draw-command */
```

4.6.3. The "hammered" string. These occur in pianos or hammered dulcimers. We return to our basic solution

$$
\psi_{k}(x, t)=a_{k} \sin (k x)\left(b_{k} \sin (k t)+c_{k} \cos (k t)\right)
$$

Since $\psi(x, 0)=0$, we set the $c_{k}$ to 0 , so our basic solution looks like

$$
\psi_{k}(x, t)=a_{k} \sin (k x) \sin (k t)
$$

and

$$
\frac{\partial \psi}{\partial t}=a_{k} \cdot k \sin (k x) \cos (k t)
$$

If we set $t=0$, this becomes

$$
\left.\frac{\partial \psi}{\partial t}\right|_{t=0}=a_{k} \cdot k \sin (k x)
$$

If $h(x)$ is our "hammering" function - the state of motion of the string at time 0 - to solve the wave equation we
(1) expand $h(x)$ in a Fourier sine-series as in the plucked case, with coefficients

$$
a_{k}=\frac{2}{\pi} \int_{0}^{\pi} h(x) \sin (k x) d x
$$

(2) the resulting series for $\psi(x, t)$ is

$$
\psi(x, t)=\sum_{k=1}^{\infty} \frac{a_{k}}{k} \sin (k x) \sin (k t)
$$

For instance, we can define our hammering function by

$$
h(x)= \begin{cases}0 & \text { if } 0 \leq x<1 / 2 \\ 1 & \text { if } 1 / 2 \leq x \leq 3 / 4 \\ 0 & \text { if } 3 / 4<x \leq \pi\end{cases}
$$

```
h(x):=block ([],
if (x<1/2) then return (0),
if (x<=3/4) then return (1),
0
);
```

and, to check this, we plot it. We define

```
a(k):=(2/% pi)*integrate ( sin (k*x), x,1/2,3/4)
```

Now we define

```
psi_h(x,t):= sum(a(j)*\operatorname{sin}(j*x)*\operatorname{sin}(j*t)/j,j,1,100)
```

and plot it with

```
with_slider_draw(
    t, /*variable to attach to the slider */
    makelist(j,j,0,100), /* list of integers */
    explicit(psi_h(x,.1*t),x,0,%pi), /* plot */
    yrange = [-1/2,1/2] /*optional graphic command *
    ); /* end of with_slider_draw-command */
```

You will benefit from memoizing these computations (as with the heat equation).

## EXERCISES.

1. Find a closed-form solution of the wave-equation for a hammered string.

4.6.4. The two-dimensional case. In this case, the wave equation looks like

$$
\frac{\partial^{2} \psi}{\partial x^{2}}+\frac{\partial^{2} \psi}{\partial y^{2}}=\frac{1}{c^{2}} \frac{\partial^{2} \psi}{\partial t^{2}}
$$

where $\psi(x, y, t)$ is the displacement of a rectangular drum-head. We try the trick we used before:

$$
\psi(x, y, t)=u(x) v(y) w(t)
$$

and get the equation

$$
\frac{d^{2} u}{d x^{2}} v(y) w(t)+u(x) \frac{d^{2} v}{d y^{2}} w(t)=\frac{1}{c^{2}} u(x) v(y) \frac{d^{2} w}{d t^{2}}
$$

and divide by $u(x) v(y) w(t)$ to get

$$
\frac{1}{u(x)} \frac{d^{2} u}{d x^{2}}+\frac{1}{v(y)} \frac{d^{2} v}{d y^{2}}=\frac{1}{c^{2}} \frac{1}{w(t)} \frac{d^{2} w}{d t^{2}}
$$

As before, functions of $x$ and $y$ can only equal a function of $t$ if they are equal to the same constant:

$$
\begin{array}{r}
\frac{1}{c^{2}} \frac{1}{w(t)} \frac{d^{2} w}{d t^{2}}=-\lambda \\
\frac{1}{u(x)} \frac{d^{2} u}{d x^{2}}+\frac{1}{v(y)} \frac{d^{2} v}{d y^{2}}=-\lambda
\end{array}
$$

The second of these equations implies that

$$
\frac{1}{u(x)} \frac{d^{2} u}{d x^{2}}=-\lambda-\frac{1}{v(y)} \frac{d^{2} v}{d y^{2}}
$$

so, again, we have a function of $x$ equal to a function of $y$ : they must both equal the same constant! We have equations

$$
\begin{aligned}
\frac{1}{c^{2}} \frac{1}{w(t)} \frac{d^{2} w}{d t^{2}} & =-(a+b) \\
\frac{1}{u(x)} \frac{d^{2} u}{d x^{2}} & =-a \\
\frac{1}{v(y)} \frac{d^{2} v}{d y^{2}} & =-b
\end{aligned}
$$

Note that the solutions to the differential equations are

$$
\begin{align*}
& u(x)=r \sin (\sqrt{a} x)+s \cos (\sqrt{a} x)  \tag{4.6.3}\\
& v(y)=r^{\prime} \sin (\sqrt{b} y)+s^{\prime} \cos (\sqrt{b} y) \\
& w(t)=\bar{r} \sin (c \sqrt{a+b} t)+\bar{s} \cos (c \sqrt{a+b} t)
\end{align*}
$$

FIGURE 4.6.3. Initial position of a two dimensional membrane

Suppose our vibrating surface is $L$ units long, $W$ units wide, and is rigidly fixed on its boundaries. We'll also suppose the membrane is at rest initially and has a shape given by $f(x, y)$, so

$$
\begin{aligned}
& f(0, y)=f(L, y)=0 \\
& f(x, 0)=f(x, W)=0
\end{aligned}
$$

We can expand $f(x, y)$ in a two-dimensional Fourier series

$$
\sum_{n, m=1}^{\infty} c_{n, m} \sin \left(\frac{n \pi x}{L}\right) \sin \left(\frac{m \pi y}{W}\right)
$$

where

$$
c_{n, m}=\frac{4}{L W} \int_{0}^{L} \int_{0}^{W} f(x, y) \sin \left(\frac{n \pi x}{L}\right) \sin \left(\frac{m \pi y}{W}\right) d x d y
$$

So equations 4.6.3 on the facing page imply that an elementary solution looks like

$$
\begin{equation*}
\sin \left(\frac{n \pi x}{L}\right) \sin \left(\frac{m \pi y}{W}\right) \cos \left(c \pi t \sqrt{\frac{n^{2}}{L^{2}}+\frac{m^{2}}{W^{2}}}\right) \tag{4.6.4}
\end{equation*}
$$

We will assume $W=1, L=2, c=1$, and define $f(x, y)=x y\left(1-x^{2}\right)\left(8-y^{3}\right)$, which plots as figure 4.6.3

```
declare(n,integer);
declare(m,integer);
coef[n,m]:=2*integrate(integrate( }x*y*(1-\mp@subsup{x}{}{\wedge}2)
    (8-y^3)*\operatorname{sin}(%\textrm{pi}*\textrm{n}*\textrm{x})*\operatorname{sin}(%\textrm{pi}*m*y/2),
    x,0,1),y,0,2);
```

which gives

$$
\operatorname{coef}(n, m)=-\frac{12\left(-\frac{\left(384 \pi^{2} m^{2}-768\right)(-1)^{m}}{\pi^{5} m^{5}}-\frac{768}{\pi^{5} m^{5}}\right)(-1)^{n}}{\pi^{3} n^{3}}
$$

Now we write a function to add up terms of the two-dimensional Fourier series

Figure 4.6.4. First three terms of a two-dimensional Fourier series

```
first_n(n, x,y):= block (
    [],
    sum(sum(
    coef[i,j]*\operatorname{sin}(%\textrm{pi}*\textrm{i}*\textrm{x})*\operatorname{sin}(%\textrm{pi}*\textrm{j}*\textrm{y}/2)
    ,i,1,n),j,1,n))
```

If we plot the first three terms, via

```
plot3d(first_n(3,x,y),[x,0,1],[y,0,2]);
```

we get figure 4.6.4, which is not bad.
Now we apply equation 4.6 .4 on the previous page to get a solution of the wave equation

$$
\sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \operatorname{coef}(n, m) \sin (n \pi x) \sin \left(\frac{m \pi y}{2}\right) \cos \left(\pi t \sqrt{n^{2}+\frac{m^{2}}{4}}\right)
$$

which we code up via

```
vibrate_n(n, x,y,t):= block (
    [],
    sum(sum(
        coef[i,j]*\operatorname{sin}(%pi*i*x)
            * sin(%pi*j*y/2)
            * cos(%pi*t*sqrt(i^2+j^2/4))
        ,i,1,n),j,1,n))
```

At time $t=.4$, our plot

```
plot3d(vibrate_n(3,x,y,.4),[x,0,1],[y,0,2]);
```

looks like figure 4.6 .5 on the facing page. Notice that the vibration is asymmetric (you might have to rotate it a bit to see this).

Figure 4.6.5. After . 4 time units

## ExERCISES.

2. Show that

$$
\int_{-\pi}^{\pi} \int_{\pi}^{\pi} \sin (n x) \sin (m y) \cdot \sin (\bar{n} x) \sin (\bar{m} y) d x d y=0
$$

if $n \neq \bar{n}$ or $m \neq \bar{m}$.

## CHAPTER 5

## Integral transforms

"We are rag dolls made out of many ages and skins, changelings who have slept in wood nests or hissed in the uncouth guise of waddling amphibians. We have played such roles for infinitely longer ages than we have been men. Our identity is a dream. We are process, not reality, for reality is an illusion of the daylight the light of our particular day."

- Loren Eiseley.

### 5.1. The Fourier Transform

In this chapter we will begin by approaching Fourier series from another direction, using the simple fact that

$$
\int_{-\pi}^{\pi} e^{i n x} \cdot e^{-i m x} d x= \begin{cases}2 \pi & \text { if } n=m \\ 0 & \text { otherwise }\end{cases}
$$

If $f(x)$ is a function, we can compute coefficients via

$$
a_{k}=\frac{1}{2 \pi} \int_{-\pi}^{\pi} f(x) e^{-i k x} d x
$$

and get a series

$$
f(x)=\sum_{k>-\infty}^{\infty} a_{k} e^{i k x}
$$

If we expand our old friend, $f(x)$, defined in equation 3.1.1 on page 32 , we get

$$
a_{k}=\frac{1}{2 \pi}\left(\int_{-1}^{0} e^{-i k x} d x+\int_{0}^{1} x^{2} e^{-i k x} d x\right)
$$

or

```
a[k]:= (integrate(%e^(-%i*k*x),x,-1,0)
+integrate( }\mp@subsup{x}{}{\wedge}2*%\mp@subsup{e}{}{\wedge}(-%i*k*x),x,0,1))/(2*% pi
```

first_n $(k, x):=\operatorname{sum}\left(a[j] * \% e^{\wedge}(\% i * j * x), j,-k, k\right)$;

Now, suppose we want to expand our horizons from $[-\pi, \pi]$ to $[-L, L]$. We rewrite the equations above to

$$
a_{k}=\frac{1}{2 L} \int_{-L}^{L} f(x) e^{-i 2 \pi k x / L} d x
$$

and the Fourier series becomes

$$
f(x)=\sum_{k>-\infty}^{\infty} a_{k} e^{2 \pi i k x / L}
$$

and we will rewrite this slightly

$$
a_{k / L}=\int_{-L}^{L} f(x) e^{-2 \pi i x k / L} d x
$$

and

$$
f(x)=\frac{1}{2 L} \sum_{k>-\infty}^{\infty} a_{k / L} e^{2 \pi i k x / L}
$$

Now, we let $L \rightarrow \infty$ and set $s=k / L$ and get

$$
\begin{gathered}
a_{s}=a(s)=\int_{-\infty}^{\infty} f(x) e^{-2 \pi i x s} d x \\
f(x)=\int_{-\infty}^{\infty} a(s) e^{2 \pi i x s} d s
\end{gathered}
$$

and $a(s)$ is defined to be the Fourier Transform of $f(x)$ - if these integrals are well-defined!

Let's compute the Fourier transform of our old friend, $f(x)$, defined in 3.1.5 on page 33 and plotted in figure 3.1.8 on page 35.

$$
a(s)=\int_{-1}^{0} e^{-2 \pi i x s} d x+\int_{0}^{1} x^{2} e^{-2 \pi i x s} d x
$$

or

```
a(s):= integrate(%e^(-2*% pi*%i*s*x),x, -1,0)
+integrate( }\mp@subsup{x}{}{\wedge}2*%\mp@subsup{e}{}{\wedge}(-2*% pi*%i*s*x), x,0,1
```

Now we plot the real and imaginary parts of $a(s)$

```
plot2d([realpart(a(s)),imagpart(a(s))],[s, -4,4]);
```

to get figure 5.1.1 on the facing page. The plot-command complains about division by zero, although it manages to generate the plot.

To see why, do indefinite integrals:
integrate (\%e^( $-2 * \% \mathrm{pi} * \% \mathrm{i} * \mathrm{~s} * \mathrm{x}), \mathrm{x})$
gives

$$
\frac{i e^{-2 \pi i x s}}{2 \pi s}
$$

integrate ( $\left.x^{\wedge} 2 * \% \mathrm{e}^{\wedge}(-2 * \% \mathrm{pi} * \% \mathrm{i} * \mathrm{~s} * \mathrm{x}), \mathrm{x}\right)$
gives

$$
\frac{\left(2 \pi^{2} i s^{2} x^{2}+2 \pi s x-i\right) e^{-2 \pi i x s}}{4 \pi^{3} s^{3}}
$$

with $s$ in the denominator in both cases! On the other hand $a(0)$ is a perfectly well-defined $4 / 3$, as the plot shows.

We have effectively decomposed $f(x)$ into a continuous infinity of periodic functions. The Fourier transform recognizes periodic behavior of a function and gives its intensity at different frequencies.

Figure 5.1.1. Fourier transform of $f(x)$

### 5.2. The discrete Fourier transform

Although Maxima doesn't have built-in commands to implement Fourier transforms analytically, it does implement fast numeric algorithms for discrete Fourier transforms.

If $\left\{x_{j}\right\} i=1 \ldots n$ is a sequence of numbers, its discrete Fourier transform is defined via

$$
\begin{equation*}
y(k)=\frac{1}{n} \sum_{j=0}^{n-1} x(j) e^{2 \pi i \cdot j k / n} \tag{5.2.1}
\end{equation*}
$$

and its inverse is defined by

$$
\begin{equation*}
x(j)=\sum_{j=0}^{n-1} y(k) e^{-2 \pi i \cdot j k / n} \tag{5.2.2}
\end{equation*}
$$

These are the definitions used by Maxima; there are many others. Many (most?) authors swap these definitions - they define the Fourier transform via equation 5.2.2 and the inverse via 5.2.1.

Although these are straightforward enough, they become cumbersome when the sequences are long (as they are in practice). An algorithm was discovered when $n=2^{m}$ for some integer $m>0$ - attributed to Cooley and Tukey (but really discovered centuries earlier by Gauss!), called the Fast Fourier Transform.

James William Cooley (1926-2016) was an American mathematician. He was a programmer on John von Neumann's computer at the Institute for Advanced Study, Princeton, NJ, from 1953 to 1956, where he notably programmed the Blackman-Tukey transformation.
He worked on quantum mechanical computations at the Courant Institute, New York University, from 1956 to 1962, when he joined the Research Staff at the IBM Watson Research Center, Yorktown Heights, NY. Upon retirement from IBM in 1991, he joined the Department of Electrical Engineering, University of Rhode Island, Kingston, where he served on the faculty of the computer engineering program.

John Wilder Tukey (1915-2000) ) was an American mathematician and statistician, best known for the development of the fast Fourier Transform (FFT) algorithm and box plot. The Tukey range test, the Tukey lambda distribution, the Tukey test of additivity, and the Teichmüller-Tukey lemma all bear his name. He is also credited with coining the term 'bit' and the first published use of the word 'software'.

The Fast Fourier Transform commands occur in a library loaded via

```
load("fft")
```

The most basic commands in question are fft and inverse_fft. The following code shows that they really are inverses.

```
load ("fft");
fpprintprec : 4; /* number of digits to print */
L : [1, 1 + %i, 1 - %i, -1, -1, 1 - %i, 1 + %i, 1];
L1 : fft (L);
[0.5, 0.5, 0.25 %i - 0.25, (- 0.3536 %i) - 0.3536, 0.0,
    0.5,(- 0.25 %i) - 0.25, 0.3536 %i + 0.3536]
L2 : inverse_fft (L1);
[1.0, 1.0 %i + 1.0, 1.0 - 1.0 %i, - 1.0, - 1.0,
    1.0 - 1.0 %i,1.0 %i + 1.0, 1.0]
lmax (abs (L2 - L));
    0.0
```

The most straightforward application of the discrete Fourier transform is detecting periodic behavior in sequences of numbers.

To introduce a more interesting (and widely-used) application, we need:

Definition 5.2.1. Let $A=\left\{a_{i}\right\}, i=0, \ldots, n-1$ and $B=\left\{b_{j}\right\}, j=$ $0, \ldots m-1$ be sequences of numbers. The convolution $A \star B=\left\{c_{k}\right\}, k=$ $0, \ldots, n+m-1$ of these sequences is defined by

$$
c_{t}=\sum_{i=0}^{t} a_{i} b_{t-i}
$$

where $a_{i}=0$ if $i \notin 0, \ldots n-1$ and $b_{j}=0$ if $j \notin 0, \ldots, m$.
REMARK. This also well-defined in the continuous case

$$
f \star g(s)=\int_{-\infty}^{\infty} f(x) g(s-x) d x
$$

We have the well known
THEOREM 5.2.2 (Convolution Theorem). If $A$ is a sequence of numbers, let $\mathcal{F}(A)$ denote the discrete Fourier transform of $A$. If $A$ and $B$ are finite sequences of numbers of length $n$, then $\mathcal{F}(A \star B)_{i}=n \cdot \mathcal{F}(A)_{i} \cdot \mathcal{F}(B)_{i}$ for all $i$. In particular

$$
\begin{equation*}
A \star B=n \cdot \mathcal{F}^{-1}(\mathcal{F}(A) \cdot \mathcal{F}(B)) \tag{5.2.3}
\end{equation*}
$$

where ' $\cdot$ ' represents element-by-element multiplication.

REMARK. See [34] for a proof. So Fourier transforms convert convolutions into simple multiplications. If we follow the widespread convention mentioned above, the factor of $n$ is unnecessary. In other words, using Maxima's conventions

$$
\begin{equation*}
A \star B=\mathcal{F}\left(\mathcal{F}^{-1}(A) \cdot \mathcal{F}^{-1}(B)\right) \tag{5.2.4}
\end{equation*}
$$

A similar result is true in the continuous case (without the factor of $n$ !).
The fast Fourier transformation and its inverse are so fast, equation 5.2.3 on the preceding page is faster than direct computation - at least if the sequences are sufficiently large.

The reader might ask
Why do we care about convolutions?
They have applications to
(1) Analyzing signals.
(2) Multiplication of polynomials (the coefficients of the product are a convolution of the coefficients of the factors), if the polynomials are large (hundreds of terms).
(3) Multiplication of numbers with hundreds of digits - we can regard them as polynomials evaluated at 10 with coefficients that are integers $0 \ldots 9$.

EXAMPLE 5.2.3. Suppose we want to form the convolution of the sequences

$$
\{1,4,2,5\} \text { and }\{3,1,3,2\}
$$

representing coefficients of cubic polynomials $1+4 x+2 x^{2}+5 x^{3}$ and $3+$ $x+3 x^{2}+2 x^{3}$. Their convolution will be of length 7 so we extend these to length $8=2^{3}$ by zeroes on the right and execute the code:

```
load ("fft");
fpprintprec : 4; /* number of digits to print */
A : [ [ , 4,2,5,0,0,0,0];
B : [3,1,3,2,0,0,0,0];
fa : fft(A);
fb : fft(B);
fc:fa*fb;/* element by element multiplication */
C : realpart(8*inverse_fft(fc));
```

You will notice that the output of the inverse_fft command has imaginary parts that are very small $\left(\sim 10^{-17}\right)$. All the intermediate computations used complex numbers that don't quite cancel in the end due to round-off errors. The simplest way to deal with these is to take the realpart.

There are other Maxima commands to take transforms of real-valued sequences (with a faster algorithm) or to use bfloat's in the computations (so the round-off errors are much smaller).

## EXERCISES.

1. Show that convolution is commutative and associative. In other words, if $A, B$, and $C$ are sequences of numbers, show that

$$
\begin{aligned}
A \star B & =B \star A \\
A \star(B \star C) & =(A \star B) \star C
\end{aligned}
$$

2. In example 5.2.3 on the preceding page, why did we extend the sequences until they had length 8 ?
3. Run example 5.2.3 on the previous page using equation 5.2.4 on the preceding page.
4. Compute the cube of the polynomial $2-4 x+x^{2}-x^{3}$ using convolution and equation 5.2.4 on the previous page.

### 5.3. The Laplace Transform

The Fourier transform inspired Laplace to develop a variation of it that is useful in solving linear differential equations. The Laplace Transform of a function, $f(x)$, is defined by

$$
\begin{equation*}
\mathcal{L}(f)(s)=\int_{0}^{\infty} e^{-s x} f(x) d x \tag{5.3.1}
\end{equation*}
$$

(if the integral is well-defined!) with an inverse

$$
\mathcal{L}^{-1}(F)(x)=\lim _{T \rightarrow \infty} \frac{1}{2 \pi i} \int_{\gamma-i T}^{\gamma+i T} e^{x s} F(s) d s
$$

where $\gamma$ is a real number set to something that makes the integral converge (if possible!).

Pierre-Simon, marquis de Laplace (1749-1827) was a French scholar whose work was important to the development of engineering, mathematics, statistics, physics, astronomy, and philosophy. He summarized and extended the work of his predecessors in his five-volume Mécanique céleste (Celestial Mechanics) (1799-1825). This work translated the geometric study of classical mechanics to one based on calculus, opening up a broader range of problems. In statistics, the Bayesian interpretation of probability was developed mainly by Laplace.
Laplace formulated Laplace's equation, and pioneered the Laplace transform which appears in many branches of mathematical physics, a field that he took a leading role in forming. The Laplacian differential operator, widely used in mathematics, is also named after him. He restated and developed the nebular hypothesis of the origin of the Solar System and was one of the first scientists to suggest an idea similar to that of a black hole. Laplace is regarded as one of the greatest scientists of all time. Sometimes referred to as the French Newton or Newton of France, he has been described as possessing a phenomenal natural mathematical faculty superior to that of almost all of his contemporaries. He was Napoleon's examiner when Napoleon attended the École Militaire in Paris in 1784. Laplace became a count of the Empire in 1806 and was named a marquis in 1817, after the Bourbon Restoration.

Both the Laplace transform and its inverse are built in to Maxima (it's not necessary to load any libraries):

```
laplace(x^3,x,s); /* The Laplace transform. */
```

gives

```
        \frac{6}{s}
```

ilt (6/s^4,s,x); /* The Inverse Laplace transform. */

## recovers $x^{3}$.

As we said earlier, the Laplace Transform is useful in solving linear differential equations. To see why, note that

$$
\mathcal{L}\left(f^{\prime}(x)=s \cdot \mathcal{L}(f)-f(0)\right.
$$

which you can see by integrating equation 5.3 .1 on the facing page by parts or typing

```
laplace('diff(f(x),x),x,s);
```

to get

```
s*laplace(f(x),x,s)-f(0)
```

Suppose we want to solve the differential equation of a harmonic oscillator as in figure 5.3.1 on the next page.

Figure 5.3.1. Harmonic oscillator
We assume the mass bobs back and forth without friction and get a differential equation like

$$
\begin{equation*}
\frac{d^{2} f}{d x^{2}}+3 f=0 \tag{5.3.2}
\end{equation*}
$$

where $f$ is the displacement of the mass and $x$ is time. We apply the Laplace Transform to get

$$
-f^{\prime}(0)+s^{2} \mathcal{L}(f)+3 \mathcal{L}(f)-s f(0)=0
$$

and solve for $\mathcal{L}(f)$ to get

$$
\mathcal{L}(f)=\frac{s f(0)+f^{\prime}(0)}{s^{2}+3}
$$

The command

$$
\text { ilt }\left((s * f(0)+f p(0)) /\left(s^{\wedge} 2+3\right), s, x\right)
$$

shows that

$$
f(x)=\frac{f^{\prime}(0) \sin (\sqrt{3} x)}{\sqrt{3}}+f(0) \cos (\sqrt{3} x)
$$

Figure 5.3.2 on the facing page shows a plot of the motion when $f^{\prime}(0)=0$ and $f(0)=1$.

FIGURE 5.3.2. Simple harmonic motion

Now consider the case of a forcing function:

$$
\frac{d^{2} f}{d x^{2}}+3 f=\sin (2 x)
$$

Here, the function $\sin (2 x)$ is driving the oscillator. We apply the Laplace Transform to both sides of the equation to get

$$
\begin{equation*}
-f^{\prime}(0)+s^{2} \mathcal{L}(f)+3 \mathcal{L}(f)-s f(0)=\frac{2}{s^{2}+4} \tag{5.3.3}
\end{equation*}
$$

We can solve this for $\mathcal{L}(f)$ (using solve!) to get

$$
\mathcal{L}(f)=\frac{f(0) s^{3}+f^{\prime}(0) s+4 s f(0)+4 f^{\prime}(0)+2}{s^{4}+7 s^{2}+12}
$$

Now we take the inverse Laplace Transform to get

$$
f(x)=\frac{\left(f^{\prime}(0)+2\right) \sin (\sqrt{3} x)}{\sqrt{3}}+f(0) \cos (\sqrt{3} x)-\sin (2 x)
$$

One nice aspect of this solution is that it explicitly shows the effect of initial conditions.

If $f^{\prime}(0)=0$ and $f(0)=1$, we get the motion in figure 5.3.3 on the next page.

One shortcoming of the Maxima's Laplace transform package is its failure to deal with Hearyside functions. These are functions of the form $H(x-\alpha)$ where $H(x)$ is defined by

$$
H(x)= \begin{cases}0 & \text { if } x<0 \\ 1 & \text { if } x \geq 0\end{cases}
$$

These are interesting because:
$\triangleright$ every piecewise-defined function can be expressed as a linear combination of Heavyside functions and ordinary functions

Figure 5.3.3. Forced harmonic motion
$\triangleright$ Laplace transforms of such functions can be easily calculated
Lemma 5.3.1. Let $f(x)$ be a function that has a Laplace transform and let $\alpha \in \mathbb{R}$ be such that $\alpha \geq 0$. Then

$$
\begin{equation*}
\mathcal{L}(H(x-\alpha) f(x))=e^{-\alpha s} \mathcal{L}(f(x+\alpha)) \tag{5.3.4}
\end{equation*}
$$

It follows that

$$
\begin{equation*}
\mathcal{L}^{-1}\left(e^{-\alpha s} g(s)\right)=H(x-\alpha) \cdot \mathcal{L}^{-1}(g)(x-\alpha) \tag{5.3.5}
\end{equation*}
$$

Proof. From the definition

$$
\begin{aligned}
\mathcal{L}(H(x-\alpha) f(x)) & =\int_{0}^{\infty} e^{-x s} H(x-\alpha) f(x) d x \\
& =\int_{\alpha}^{\infty} e^{-x s} f(x) d x
\end{aligned}
$$

Now let $u=x-\alpha$, so $x=u+\alpha$ and substitute

$$
\begin{aligned}
\int_{\alpha}^{\infty} e^{-x s} f(x) d x & =\int_{0}^{\infty} e^{-(u+\alpha) s} f(u+\alpha) d x \\
& =e^{-\alpha s} \int_{0}^{\infty} e^{-u s} f(u+\alpha) d x \\
& e^{-\alpha s} \mathcal{L}(f(u+\alpha))
\end{aligned}
$$

EXAMPLE 5.3.2. Suppose the driving force of our harmonic oscillator is given by

$$
d(x)= \begin{cases}1 & \text { if } 1 / 2 \leq x \leq 1 \\ 0 & \text { otherwise }\end{cases}
$$

Then $d(x)=H(x-1 / 2)-H(x-1)$ and our version of equation 5.3.3 on the preceding page is

$$
-f^{\prime}(0)+s^{2} \mathcal{L}(f)+3 \mathcal{L}(f)-s f(0)=e^{-s / 2}-e^{-s}
$$

giving

$$
\begin{align*}
\mathcal{L}(f) & =\frac{s f(0)+f^{\prime}(0)+e^{-s / 2}-e^{-s}}{s^{2}+3} \\
& =\frac{s}{s^{2}+3} f(0)+\frac{1}{s^{2}+3} f^{\prime}(0)+\frac{e^{-s / 2}}{s^{2}+3}-\frac{e^{-s}}{s^{2}+3} \tag{5.3.6}
\end{align*}
$$

Now we isolate each term of the form

$$
\mathbf{e}^{-\mathbf{a s}} r(s)
$$

where $a$ is a real number and compute

$$
H(x-a) \mathcal{L}^{-1}(r)(x-a)
$$

In the case of equation 5.3.6, we take the inverse Laplace transform using the ilt-command for the first two terms, and the ilt-command coupled with equation 5.3.5 on the facing page to handle the remaining two terms:

$$
\begin{aligned}
f(x)= & \cos (\sqrt{3} \cdot x) f(0)+\frac{\sin (\sqrt{3} \cdot x)}{\sqrt{3}} f^{\prime}(0) \\
& +H(x-1 / 2) \cdot \frac{\sin (\sqrt{3} \cdot(x-1 / 2))}{\sqrt{3}} \\
& -H(x-1) \cdot \frac{\sin (\sqrt{3} \cdot(x-1))}{\sqrt{3}}
\end{aligned}
$$

If we assume that the string was initially at rest, we get

$$
f(x)=H(x-1 / 2) \cdot \frac{\sin (\sqrt{3} \cdot(x-1 / 2))}{\sqrt{3}}-H(x-1) \cdot \frac{\sin (\sqrt{3} \cdot(x-1))}{\sqrt{3}}
$$

which is plotted in figure 5.3.4 on the next page. Here, we have coded

```
H(x):= block (
    [],
    if (x>=0) then return (1),
    0)
```

## EXERCISES.

1. Is the function depicted in figure 5.3 .3 on the facing page periodic?
2. Represent the piecewise function

$$
f(x)= \begin{cases}0 & \text { if } x<2 \\ x^{2} & \text { if } x<3 \\ -x & \text { if } x<5 \\ 0 & \text { if } x \geq 5\end{cases}
$$

as a linear combination of Heavyside functions (the coefficients may be arbitrary ordinary functions).

Figure 5.3.4. Discontinuous driving force
3. Use Laplace transforms to solve the differential equation

$$
\frac{d^{2} y}{d x^{2}}+\frac{d y}{d x}+x=f(x)
$$

where $f(x)$ is defined in exercise 2 on the previous page.

## CHAPTER 6

## Orthogonal polynomials

#### Abstract

"It is a matter for considerable regret that Fermat, who cultivated the theory of numbers with so much success, did not leave us with the proofs of the theorems he discovered. In truth, Messrs Euler and Lagrange, who have not disdained this kind of research, have proved most of these theorems, and have even substituted extensive theories for the isolated propositions of Fermat. But there are several proofs which have resisted their efforts." - Adrien-Marie Legendre.

### 6.1. Introduction

As we saw in section 4.3 on page 52, it is possible to expand functions (even discontinuous ones!) in a series of sines and cosines. How was this possible? After some thought, it becomes clear that the key was equations 4.3 .3 on page $53,4.3 .5$ on page 54 , and 4.3 .7 on page 54 - the so-called orthogonality relations.

Is it possible to find similar relations between other sets of functions?
We will construct a set of orthogonal polynomials $\left\{P_{i}(x)\right\}$ with

$$
\begin{equation*}
\int_{-1}^{1} P_{i}(x) P_{j}(x) d x=0 \tag{6.1.1}
\end{equation*}
$$

if $i \neq j$.
The simplest candidate for $P_{0}$ is 1 , so we will pick it. The linear polynomial is of the form $a_{0}+a_{1} x$

$$
\int_{-1}^{1} 1 \cdot\left(a_{0}+a_{1} x\right) d x=2 a_{0}
$$

For the polynomials to be orthogonal, we set $a_{0}=0$ and set $a_{1}=1$, so $p_{1}(x)=x$. We also have

$$
\int_{-1}^{1} P_{1}(x)^{2} d x=\frac{2}{3}
$$

The general form of $P_{2}(x)$ is $a_{0}+a_{1} x+a_{2} x^{2}$. We get
integrate ( $\left.1 *\left(a_{-} 0+a_{-} 1 * x+a_{-} 2 * x^{\wedge} 2\right), x,-1,1\right) ;$ ratsimp $(\%)$;
which gives

$$
\frac{2 a_{2}+6 a_{0}}{3}
$$

integrate $\left(x *\left(a \_0+a_{-} 1 * x+a_{-} 2 * x^{\wedge} 2\right), x,-1,1\right) ;$ ratsimp $(\%)$;

Figure 6.1.1. Model for Legendre polynomials
gives

$$
\frac{2 a_{1}}{3}
$$

We uniquely determine coefficients by requiring $P_{i}(1)=1$ :
solve ([2*a_2+6*a_0=0,2*a_1=0,a_0+a_1+a_2=1],
[a_0,a_1, a_2])
and get

$$
\left[\left[a_{0}=-\frac{1}{2}, a_{1}=0, a_{2}=\frac{3}{2}\right]\right]
$$

so

$$
P_{2}(x)=\frac{3}{2} x^{2}-\frac{1}{2}
$$

In this fashion, we can inductively construct a sequence of polynomials $\left\{P_{i}(x)\right\}$ satisfying equation 6.1.1 on the preceding page. Of course, we are not the first people to think of this. The $\left\{P_{i}(x)\right\}$ are called the Legendre Polynomials after the first person to study them.

Adrien-Marie Legendre (1752-1833) was a French mathematician who made numerous contributions to mathematics. Well-known and important concepts such as the Legendre polynomials and Legendre transformation are named after him.
In 1782 , he first introduced his polynomials as coefficients in the expansion of the Newtonian Potential energy

$$
\begin{align*}
\frac{1}{\left|\mathbf{x}-\mathbf{x}^{\prime}\right|} & =\frac{1}{\sqrt{|\mathbf{x}|^{2}+\left|\mathbf{x}^{\prime}\right|^{2}-2|\mathbf{x}|\left|\mathbf{x}^{\prime}\right| \cos \theta}}  \tag{6.1.2}\\
& =\sum_{\ell=0}^{\infty} \frac{\left|\mathbf{x}^{\prime}\right|^{\ell}}{|\mathbf{x}|^{\ell+1}} P_{\ell}(\cos \theta)
\end{align*}
$$

where $\theta$ is the angle between the vectors $\mathbf{x}$ and $\mathbf{x}^{\prime}$, and $\left|\mathbf{x}^{\prime}\right|<|\mathbf{x}|$ - see figure 6.1.1.
Figure 6.1.2 on the facing page show plots of the first six Legendre polynomials.

Nowadays, they crop up when one converts the heat and wave equations to spherical coordinates (latitude, longitude, and radius). Since the

Figure 6.1.2. The first six Legendre polynomials

Schrödinger Wave equation is related to the Heat equation, Legendre polynomials also are widely used in Quantum Mechanics.

Legendre and others have discovered some of their properties:
Besides orthogonality, we have

$$
\begin{equation*}
\int_{-1}^{1} P_{n}(x)^{2} d x=\frac{2}{2 n+1} \tag{6.1.3}
\end{equation*}
$$

(this isn't obvious!).
Luckily, people have compiled a Maxima library of Legendre polynomials (and many other systems of orthogonal polynomials) accessed by

```
load("orthopoly")
```

The Legendre polynomials are given by legendre_p(n,x). If we type

```
legendre_p (5,x)
```

we get

$$
-15(1-x)-\frac{63(1-x)^{5}}{8}+\frac{315(1-x)^{4}}{8}-70(1-x)^{3}+\frac{105(1-x)^{2}}{2}+1
$$

and expand (\%) gives a simplified form

$$
\frac{63 x^{5}}{8}-\frac{35 x^{3}}{4}+\frac{15 x}{8}
$$

Recall our old friend, the discontinuous function $f(x)$, plotted in 3.1.8 on page 35:

```
f(x) := block ([], /* no local variables */
if(x<-1) then return (0),
```

Figure 6.1.3. First 5 terms of a Legendre series

```
if(x<0) then return (1),
if(x<=1) then return ( }\mp@subsup{x}{}{\wedge}2)\mathrm{ ,
0); /*default final value */
```

We'll expand this in a series of Legendre polynomials using the same methods as for Fourier series:

$$
a_{k}=\frac{\int_{-1}^{1} \text { legendre } \_\mathrm{p}(k, x) f(x) d x}{\int_{-1}^{1} \text { legendre } \_\mathrm{p}(k, x)^{2} d x}
$$

Translated into Maxima, this is

```
a[n]:=((2*n+1)/2)*(integrate(legendre_p (n,x), x, -1,0)
+integrate(legendre_p(n,x)*x^2,x,0,1));
```

where

$$
\frac{2 n+1}{2}=\frac{1}{\int_{-1}^{1} \text { legendre } \mathrm{p}(k, x)^{2} d x}
$$

- see equation 6.1.3 on the preceding page. We finally get our series:
partial_sum (k, x):=sum (a[n]*legendre_p (n, x), n, 0,k)
If we plot the first five terms against $f(x)$ :

```
plot2d(['f(x),partial_sum(5,x)],[x,-1,1]);
```

we get figure 6.1.3.
If we try 20 terms, we get figure 6.1.4 on the facing page. The Legendre series is clearly trying to approximate $f(x)$ - just as a Fourier series did.

As with Fourier series, it turns out ${ }^{1}$ that the Legendre series converges in the manner

$$
\lim _{n \rightarrow \infty} \int_{-1}^{1}(\text { partial_sum }(n, x)-f(x))^{2} d x=0
$$

[^16]

Figure 6.1.4. First 20 terms of a Legendre series

Many applications of Legendre polynomials come from equation 6.1.2 on page 88: if we are in spherical coordinates and have a charge situated at the end of vector $\mathbf{x}^{\prime}$, the potential energy at the end of vector $\mathbf{x}$ is expressed in the series of Legendre polynomial given above.

## EXERCISES.

1. Legendre polynomials satisfy Bonnet's Recursion Formula

$$
(n+1) P_{n+1}(x)=(2 n+1) x P_{n}(x)-n P_{n-1}(x)
$$

Write a Maxima function to compute $P_{n}(x)$, using this.
2. Expand $\sin x$ in a series of Legendre polynomials and compare with the Taylor series of the sine-function.
3. Do three-dimensional plots of $P_{2}(\cos \theta), P_{3}(\cos \theta), P_{4}(\cos \theta)$ in cylindrical coordinates, where $\theta$ is the angle from the $x-y$-plane and radius is 1.

### 6.2. Weighted orthogonality

There are many other systems of orthogonal polynomials in common use. We will only touch on a few of them.
6.2.1. Chebyshev Polynomials. We begin with Chebyshev Polynomials, $\left\{T_{n}(x)\right\}$, defined by

$$
\begin{equation*}
T_{n}(\cos \theta)=\cos n \theta \tag{6.2.1}
\end{equation*}
$$

Figure 6.2.1. The first four Chebyshev polynomials

They are orthogonal in the sense that ${ }^{2}$

$$
\int_{-1}^{1} \frac{T_{n}(x) T_{m}(x)}{\sqrt{1-x^{2}}} d x= \begin{cases}0 & \text { if }|m| \neq|n|  \tag{6.2.2}\\ \pi & \text { if } n=m=0 \\ \pi / 2 & \text { if } n=m>0\end{cases}
$$

so they are orthogonal with a weight-function

$$
\frac{1}{\sqrt{1-x^{2}}}
$$

Pafnuty Lvovich Chebyshev (Пафну́тий Льво́вич Чебышёв) (1821-1894) was a Russian mathematician and considered to be the founding father of Russian mathematics.

Figure 6.2.1 shows the first four Chebyshev polynomials.
When we expand a functions (like $f(x)$ ) in a series of Chebyshev polynomials, we must take the weight function into account:

$$
\begin{aligned}
a_{0} & =\frac{1}{\pi} \int_{-1}^{1} \frac{f(x)}{\sqrt{1-x^{2}}} d x \\
a_{k>0} & =\frac{2}{\pi} \int_{-1}^{1} \frac{f(x) T_{k}(x)}{\sqrt{1-x^{2}}} d x
\end{aligned}
$$

In Maxima's orthopoly package, they are called chebyshev_t $(\mathrm{n}, \mathrm{x})$. Our Maxima commands are and we sum up terms of the series via

```
partial_sum(k,x):=a0+sum(a[n]* chebyshev_t (n,x),n,1,k)
```

If we plot the first twenty terms against our discontinuous function $f(x)$ :

[^17]```
a0:(1/% pi )*(integrate(1/ sqrt(1-x^2), x, -1,0)
+integrate(x^2/sqrt(1-x^2),x,0,1));
a[n]:=(1/% pi ) *
(integrate(chebyshev_t (n,x)/ sqrt(1-x^2),x,-1,0)
+integrate(chebyshev_t (n,x)*x^2/sqrt(1-x^2), x,0,1));
```

Figure 6.2.2. First 20 terms of a Chebyshev expansion
plot2d(['f(x), partial_sum (20, $x)],[x,-1,1])$;
we get figure 6.2.2. The weight-function plays a part in how the Chebyshev series converges to $f(x)$. We have

$$
\lim _{n \rightarrow \infty} \int_{-1}^{1} \frac{(\text { partial_sum }(n, x)-f(x))^{2}}{\sqrt{1-x^{2}}} d x=0
$$

As figure 6.2 .3 on the following page shows, it prioritizes the endpoints of the interval $[-1,1]$.

It is known (which we won't prove!) that for continuous functions (something our $f(x)$ isn't) the Chebyshev series converges more rapidly than any other series of orthogonal polynomials - see [30]. This means they have important applications in numerical analysis. For instance many software-library functions for sines and cosines use Chebyshev expansions.
6.2.2. Laguerre Polynomials. Laguerre Polynomials are defined as certain solutions of the Laguerre Differential equation:

$$
x \frac{d^{2} y}{d x^{2}}+(1-x) \frac{d y}{d x}+n y=0
$$

where $n \geq 0$ is an integer. The only nonsingular solution of this is the $n^{\text {th }}$ Laguerre polynomial, $L_{n}(x)=$ laguerre $(n, x)$. These polynomials are orthogonal with respect to the weight function $e^{-x}$ :

$$
\int_{0}^{\infty} e^{-x} \operatorname{laguerre}(n, x) \cdot \operatorname{laguerre}(m, x) d x=0 \text { if } n \neq m
$$

Figure 6.2.3. Weight-function for Chebyshev expansions

FIGURE 6.2.4. Laguerre polynomials
and ${ }^{3}$

$$
\int_{0}^{\infty} e^{-x} \text { laguerre }(n, x)^{2} d x=1
$$

[^18]

FIGURE 6.2.5. Expansion of $f(x)$ in 100 Laguerre polynomials

Edmond Nicolas Laguerre (1834-1886) was a French mathematician and a member of the Académie des sciences (1885). His main works were in the areas of geometry and complex analysis. He also investigated orthogonal polynomials. Laguerre's method is a root-finding algorithm tailored to polynomials.

The Laguerre polynomials arise in quantum mechanics, in the radial part of the solution of the Schrödinger equation for a one-electron atom. We will expand our discontinuous function in these polynomials with coefficients

```
a0:integrate(%e^(-x)* *^2, x , 0,1);
a[n]:= integrate(laguerre (n,x)* (^^2*%e^(-x),x,0,1);
```

and partial sum

```
partial_sum (k,x):=a0+sum(a[n]* laguerre(n,x),n,1,k)
```

If we plot the first 100 terms of the series, we get figure 6.2.5, which doesn't look very good until you realize that it only converges with the weight function $e^{-x}$.

In other words

$$
\int_{0}^{\infty} e^{-x}\left|f(x)-p_{n}(x)\right| d x \rightarrow 0
$$

as $n \rightarrow \infty$, where $p_{n}(x)$ is the $n^{\text {th }}$ partial sum of a Laguerre series. Since $e^{-x}$ tapers off rapidly as $x$ increases, we don't really care what $p_{n}(x)$ does for large values of $x$.

Laguerre polynomials are often used to numerically estimate integrals of the form

$$
\int_{0}^{\infty} e^{-x} f(x) d x
$$

(for the degree- $n$ form of the equation with $n \geq 1$ ) via the Gauss-Laguerre quadrature formula

$$
\begin{equation*}
\int_{0}^{\infty} e^{-x} f(x) d x \approx \sum_{i=1}^{n} w_{i} f\left(x_{i}\right) \tag{6.2.3}
\end{equation*}
$$

where the $\left\{x_{i}\right\}$ are the roots of $L_{n}(x)$ and the weights $\left\{w_{i}\right\}$ are given by

$$
\begin{equation*}
w_{i}=\frac{x_{i}}{(n+1)^{2} L_{n+1}\left(x_{i}\right)} \tag{6.2.4}
\end{equation*}
$$

see [39].

## ExERCISES.

1. Code a function the does Gauss-Laguerre quadrature using equations 6.2.3 and 6.2.4 . Hint: use the allroots command to find the roots of $\left.L_{n}(x)\right)$.
6.2.3. Hermite polynomials. These are orthogonal with respect to the weight function $e^{-x^{2}}$. They exist in two closely-related forms, the physicist's Hermite polynomials, defined by

$$
H_{n}(x)=(-1)^{n} e^{x^{2}} \frac{d^{n}}{d x^{n}}\left(e^{-x^{2}}\right)
$$

and the probability-theorist's form

$$
H e_{n}(x)=(-1)^{n} e^{x^{2} / 2} e^{x^{2}} \frac{d^{n}}{d x^{n}}\left(e^{-x^{2} / 2}\right)
$$

We will consider the physicist's form here, which appear naturally in the Schrödinger wave equation for a harmonic oscillator in quantum mechanics.

Their orthogonality relations are

$$
\int_{-\infty}^{\infty} e^{-x^{2}} H_{n}(x) H_{m}(x) d x= \begin{cases}0 & \text { if } n \neq m \\ \sqrt{\pi} 2^{n} n! & \text { otherwise }\end{cases}
$$

In the orthopoly library, the $n^{\text {th }}$ Hermite polynomial is denoted hermite( $n, x$ ). The first five Hermite polynomials are plotted in figure 6.2.6 on the facing page.

FIGURE 6.2.6. Hermite polynomials

Charles Hermite (1822-1901) was a French mathematician who did research concerning number theory, quadratic forms, invariant theory, orthogonal polynomials, elliptic functions, and algebra.
Hermite polynomials, Hermite interpolation, Hermite normal form, Hermitian operators, and cubic Hermite splines are named in his honor. One of his students was Henri Poincaré.
He did not discover Hermite polynomials ${ }^{a}$ : Hermite polynomials were defined by Pierre-Simon Laplace in 1810 and studied in detail by Pafnuty Chebyshev in 1859. Chebyshev's work was overlooked, and they were named later after Charles Hermite, who wrote on the polynomials in 1864, describing them as new.
${ }^{a}$ See Stigler's Law of Eponymy in the index!

## ExERCISES.

2. Expand our discontinuous function, $f(x)$, (see equation 3.1.1 on page 32) in Hermite polynomials.

## CHAPTER 7

## Linear Algebra

"Life stands before me like an eternal spring with new and brilliant clothes."

- Carl Friedrich Gauss.

### 7.1. Introduction

We assume the reader is familiar with the basic concepts of linear algebra - see [40, chapter 6] as a general reference.

Initially, the focus of linear algebra was solving systems of linear equations in multiple variables. Some 4000 years ago, Babylonians were able to solve pairs of linear equations in two unknowns. In 200BC, the Chinese publication, "Nine Chapters of the Mathematical Art" (see [24]) showed how to solve systems of three equations in three unknowns.

The solve-command can handle simple systems of linear equations:
Given

$$
\begin{align*}
2 x+3 y & =5 \\
6 x-y & =2 \tag{7.1.1}
\end{align*}
$$

where we must solve for $x$ and $y$. If we type

```
solve ([2*x+3*y=5,6*x-y=2],[x,y])
```

and Maxima replies with

$$
\left[\left[x=\frac{11}{20}, y=\frac{13}{10}\right]\right]
$$

Here's another example:

$$
\begin{array}{r}
x+2 y-z=0 \\
3 x-y+2 z=0
\end{array}
$$

which we code as

$$
\text { solve }([x+2 * y-z=0,3 * x-y+2 * z=0],[x, y, z])
$$

and Maxima replies with

$$
\left[\left[x=-\frac{3 \% \mathrm{r} 1}{7}, y=\frac{5 \% \mathrm{r} 1}{7}, z=\% \mathrm{r} 1\right]\right]
$$

Here, Maxima has introduced an auxiliary variable, \%r1, that can take on arbitrary values, showing that there are an infinite number of solutions to this system.

In 1848 , Sylvester realized that an array of coefficients was all that really mattered in these equations and coined the term "matrix" for them from the Latin word for "mother" and "womb".

Coding matrices in Maxima is done with the matrix-command:
a: matrix $([1,2,3],[4,5,6],[7,8,9])$
gives

$$
\left[\begin{array}{lll}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9
\end{array}\right]
$$

The usual operations ' + ' and ' - ' work for matrices. The multiplicationoperation, ' $*^{\prime}$ multiplies them element-by-element, which is not what we want. To correctly multiply matrices, use the '.'-operator.

For instance, if we type
b: matrix ([1,2, -3],[4,5,6],[7, 8,10$])$
then
a.b
produces
$\left[\begin{array}{ccc}30 & 36 & 39 \\ 66 & 81 & 78 \\ 102 & 126 & 117\end{array}\right]$
$a+b$
produces
$\left[\begin{array}{ccc}2 & 4 & 0 \\ 8 & 10 & 12 \\ 14 & 16 & 19\end{array}\right]$
wxmaxima has a short-cut to entering matrices: select the menu-item

## Matrix $\triangleright$ Enter Matrix .

Note 7.1.1. Matrices are always assumed to be two-dimensional, even if they only have one row! So, if we define

```
a : matrix ([1,2,-3])
```

we access the elements with two subscripts,
$a[1,1]$, $a[1,2], a[1,3]$
rather than one.
Given a matrix, one can determine how many rows it has via the lengthcommand:
length (b)
returns
7.1.1. Matrix-creation commands. Besides the matrix-command, we have several others to create matrices:
(1) the ident( n )-command creates an $n \times n$ identity matrix.
(2) the zeromatrix( $\mathrm{m}, \mathrm{n}$ )-command creates an $m \times n$ matrix of zeroes.
(3) the genmatrix $($ ident $, m, n)$-command is the most powerful of the matrix-creation commands. If ident is an identifier with no other properties, genmatrix produces an $m \times n$ matrix with subscripted copies of ident. For example

```
genmatrix (a,3,4)
```

produces

$$
\left[\begin{array}{llll}
a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} \\
a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} \\
a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4}
\end{array}\right]
$$

If ident is the name of a memoized function of two variables, genmatrix plugs row and column numbers into ident and posts the value of the function to the array

```
b[i,j]:= i+j ;
genmatrix(b,3,4)
```

produces

$$
\left[\begin{array}{llll}
2 & 3 & 4 & 5 \\
3 & 4 & 5 & 6 \\
4 & 5 & 6 & 7
\end{array}\right]
$$

ident can also be an anonymous lambda-function, so

$$
\text { genmatrix (lambda }([\mathrm{i}, \mathrm{j}], \mathrm{i}-\mathrm{j}), 3,4)
$$

produces

$$
\left[\begin{array}{cccc}
0 & -1 & -2 & -3 \\
1 & 0 & -1 & -2 \\
2 & 1 & 0 & -1
\end{array}\right]
$$

7.1.2. Matrix operations. The transpose-command does what you'd expect it to do:

```
transpose(a)
```

gives

$$
\left[\begin{array}{lll}
1 & 4 & 7 \\
2 & 5 & 8 \\
3 & 6 & 9
\end{array}\right]
$$

We will also be concerned with vectors, which we will regard as matrices with a single row or, more often, a single column. The '.' operation doubles as the dot product for vectors, so

```
r:transpose(matrix ([1,2, - 3]))
```

produces

$$
\left[\begin{array}{c}
1 \\
2 \\
-3
\end{array}\right]
$$

and
s: transpose(matrix ([4, 5, 6]))
produces

Now
r.s
is undefined as a matrix-product, but gives the dot-product of r and s as vectors, namely -4 . Technically, the valid matrix product is
transpose (r). s
which also produces the dot-product, -4 .
We can write a simple function for the norm of a vector
norm(v):=sqrt(v.v);
or, the technically more correct
norm(v):=sqrt(transpose(v).v);
Matrix-assignment, like
x : b
merely causes x to become an alias for b . Changes to x like
x[2,1]:-100
will be immediately reflected in b :

$$
\left[\begin{array}{ccc}
1 & 2 & -3 \\
-100 & 5 & 6 \\
7 & 8 & 10
\end{array}\right]
$$

If we want an independent copy of a matrix, we must use the copymatrixcommand
x: copymatrix (b)
We can easily compute integral powers of matrices too: ${ }^{1}$ $a^{\wedge \wedge} 2$

[^19]produces
\[

\left[$$
\begin{array}{ccc}
30 & 36 & 42 \\
66 & 81 & 96 \\
102 & 126 & 150
\end{array}
$$\right]
\]

```
b^^-1
```

produces the inverse

$$
b^{-1}=\left[\begin{array}{ccc}
\frac{2}{15} & -\frac{44}{15} & \frac{9}{5} \\
\frac{2}{15} & \frac{31}{15} & -\frac{6}{5} \\
-\frac{1}{5} & \frac{2}{5} & -\frac{1}{5}
\end{array}\right]
$$

Definition 7.1.2. To analyze more complex linear systems, we simplify the matrix of coefficients by performing elementary row-operations:

Type 1: subtracting a multiple of one row from another. Maxima command: rowop $(M, i, j$, theta) replaces row $i$ in the matrix $M$ by row i - theta*row j.
Type 2: involves swapping two rows of a matrix. Maxima command: rowswap $(\mathrm{M}, \mathrm{i}, \mathrm{j})$ which swaps rows i and j of the matrix M .
Type 3: involves multiplying a row of a matrix by a nonzero constant. There is no Maxima command to do this.

If the matrix consists of coefficients of a linear system, these operations produce a system that is mathematically equivalent to the original. Our goal is to make the matrix triangular:

DEFINITION 7.1.3. An $n \times n$ matrix, $A$, is called upper-triangular if $A_{i, j}=$ 0 whenever $i>j$. The matrix, $A$, is lower triangular if $A_{i, j}=0$ whenever $j>i$.

REMARK. The term "upper-triangular" comes from the fact that $A$ looks like

$$
\left[\begin{array}{ccccc}
A_{1,1} & A_{1,2} & \cdots & A_{1, n-1} & A_{1, n} \\
0 & A_{2,2} & \ddots & A_{2, n-1} & A_{2, n} \\
0 & 0 & \ddots & \vdots & \vdots \\
\vdots & \vdots & \ddots & A_{n-1, n-1} & A_{n-1, n} \\
0 & 0 & \cdots & 0 & A_{n, n}
\end{array}\right]
$$

The process of converting a matrix to upper triangular form is called Gaussian Elimination.

Carl Friedrich Gauss (1777-1855) was a German mathematician and physicist who made significant contributions to many fields in mathematics and science. Sometimes referred to as the Princeps mathematicorum (Latin for "the foremost of mathematicians") and "the greatest mathematician since antiquity", Gauss had an exceptional influence in many fields of mathematics and science, and is ranked among history's most influential mathematicians.
In surveying land around Hannover, he invented many modern surveying instruments and the field of differential geometry. This paved the way for Riemannian geometry and Einstein's theory of General Relativity. He also discovered least-squares approximations (see section 7.3 .1 on page 112) for estimating orbits of planets and asteroids given many slightly differing observations. Least squares was used to predict the future location of the newly discovered asteroid, Ceres.
Ironically, Gauss didn't discover Gaussian Elimination, which was first mentioned (in Europe) by Isaac Newton. He did discover the fast Fourier transform 160 years before its official discoverers, Cooley and Tukey. This is a time-honored tradition in mathematics called Stigler's law of eponymy ${ }^{a}$ of naming results after people who didn't discover them.
${ }^{a}$ True to itself, it was first proposed by the sociologist, Robert Merton, not Stigler © ${ }^{(\cdot)}$

Maxima has a triangularize-command to do this

## triangularize (a)

produces

$$
\left[\begin{array}{ccc}
1 & 2 & 3 \\
0 & -3 & -6 \\
0 & 0 & 0
\end{array}\right]
$$

The related echelon-command produces a normalized form of this matrix with the first nonzero entry of each row set to 1 . The 1 that begins each nonzero row is called its pivot. So

## echelon (a)

produces

$$
\left[\begin{array}{lll}
\mathbf{1} & 2 & 3 \\
0 & \mathbf{1} & 2 \\
0 & 0 & 0
\end{array}\right]
$$

where we have highlighted the pivots.
To solve a linear system, we really want a reduced echelon matrix where we perform additional row-operations to make the pivot in each row the only nonzero element in its column - see figure 7.1.1 on the next page.

So
reduced_echelon (a)
subtracts $2 \times$ row 2 from row 1 to produce

$$
\left[\begin{array}{ccc}
1 & 0 & -1 \\
0 & 1 & 2 \\
0 & 0 & 0
\end{array}\right]
$$

```
/* We must write a function to compute
    reduced echelon form */
reduced_echelon(a):= block ([ rows,cols ,k,temp],
    [rows,cols]: matrix_size(a),
    temp:echelon(a), /* this copies a */
    k:min(rows,cols),
        for i thru min(rows,cols)
        /* Find pivot */
            do (if temp[i,i]=0 then (k:i-1,return())),
            /* Clear out column i */
        for i:k thru 2 step -1 do
            (for j from i-1 thru 1 step -1
                do temp:rowop(temp,j,i,temp[j,i])),
        temp) /* return the result */
```

Figure 7.1.1. Code for a reduced echelon matrix

Definition 7.1.4. If $s=\left\{v_{1}, \ldots, v_{n}\right\}$ are elements of $\mathbb{R}^{n}$, their span, $\operatorname{Span}(s)$ is the set of all possible linear combinations

$$
\sum_{i=1}^{n} \alpha_{i} v_{i}
$$

for $\alpha_{i} \in \mathbb{R}$. It forms a subspace of $\mathbb{R}^{n}$.
Recall that the column space of a matrix, $A$, is the vector space of all vectors of the form $A \mathbf{v}$ for all vectors $\mathbf{v}$. We have a columnspace-command to compute this
columnspace (a)

$$
\operatorname{span}\left(\left[\begin{array}{l}
1 \\
4 \\
7
\end{array}\right],\left[\begin{array}{l}
2 \\
5 \\
8
\end{array}\right]\right)
$$

Recall that the null space, $\operatorname{Null}(A)$, of a matrix, $A$, is the set of vectors, $\mathbf{v}$, such that $A \mathbf{v}=0$. This is the nullspace-command:

```
nullspace(a)
```

$$
\operatorname{span}\left(\left[\begin{array}{c}
-3 \\
6 \\
-3
\end{array}\right]\right)
$$

Recall that determinants are defined by
Definition 7.1.5. If $M$ is an $n \times n$ matrix, its determinant, $\operatorname{det}(M)$ is defined by

$$
\begin{equation*}
\operatorname{det}(M)=\sum_{\sigma \in S_{n}} \wp(\sigma) M_{1, \sigma(1)} \cdots M_{n, \sigma(n)} \tag{7.1.2}
\end{equation*}
$$

where the sum is taken over all $n$ ! permutations in $S_{n}$. Here $\wp(\sigma)$ is the parity of a permutation, defined in terms of the number of inversions it produces. An inversion exists for a permutation, $\sigma$, if there is a pair of elements $x, y$ such that $x<y$ and $\sigma(x)>\sigma(y)$.

$$
\wp(\sigma)= \begin{cases}+1 & \text { if the total number of inversions is even } \\ -1 & \text { otherwise }\end{cases}
$$

Remark. Equation 7.1.2 on the preceding page is due to Euler. It is not particularly suited to computation of the determinant since it is a sum of $n$ ! terms.

Definition 7.1.6. If $B=\prod_{i=1}^{n}\left[a_{i}, b_{i}\right]$ is a box in $\mathbb{R}^{n}$, its volume, $\operatorname{vol}(B)$ is defined by

$$
\operatorname{vol}(B)=\prod_{i=1}^{n}\left(b_{i}-a_{i}\right)
$$

This is used to define the Lebesgue measure:
Definition 7.1.7. If $R \subset \mathbb{R}^{n}$ is a region, its outer Lebesgue measure is defined by

$$
\begin{aligned}
& \lambda(R)= \\
& \inf \left\{\sum_{B \in \mathcal{C}} \operatorname{vol}(B): \mathcal{C} \text { is a countable set of boxes whose union covers } R\right\}
\end{aligned}
$$

Recall the geometric interpretation of the determinant:
THEOREM 7.1.8. If $A$ is an $n \times n$ matrix, $R \subset \mathbb{R}^{n}$, then

$$
\lambda(A(R))=|\operatorname{det} A| \cdot \lambda(R)
$$

REMARK. So the determinant gives the effect of a linear transformation on volumes. Analytic geometry and manifold theory considers volumes to have signs, in which case we do not take the absolute value of the determinant.

See [40] for a proof.
Maxima has a determinant-command that computes these efficiently

```
determinant(a)
```

0
determinant $(b)$
15
More recently, Fateman has implemented a newdet-command that is faster than determinant but uses more memory - see [17]. If

$$
z=\left(\begin{array}{ccc}
2 x-1 & 37 & -9 \\
3 x^{2}+x & 2 x & 3 x \\
51 & 2 x & 7
\end{array}\right)
$$

then
newdet ( z )
produces

$$
-66 x^{3}-761 x^{2}+6306 x
$$

## ExERCISES.

1. What is the volume of the parallelepiped spanned by the three vectors

$$
v_{1}=\left[\begin{array}{l}
1 \\
5 \\
6
\end{array}\right], \quad v_{2}=\left[\begin{array}{l}
2 \\
1 \\
3
\end{array}\right] \quad v_{3}=\left[\begin{array}{c}
1 \\
0 \\
-1
\end{array}\right]
$$

?
2. What might the sign of the volume mean (when a determinant has a negative sign)?

### 7.2. Changes of basis

Recall that a basis of a vector-space is like a "coordinate system" for it: every vector can be uniquely written as a linear combination of the basiselements.

Suppose we have a vector-space with basis $\left\{e_{i}\right\}, i=1, \ldots, n$ and we are given a new basis $\left\{b_{i}\right\}$. If

$$
\left[\begin{array}{c}
x_{1} \\
\vdots \\
x_{n}
\end{array}\right]
$$

is a vector in this new basis, then

$$
x_{1} b_{1}+\cdots+x_{n} b_{n}=\left[\begin{array}{lll}
b_{1} & \cdots & b_{n}
\end{array}\right] \cdot\left[\begin{array}{c}
x_{1} \\
\vdots \\
x_{n}
\end{array}\right]
$$

is the same vector in the old basis, where $P=\left[\begin{array}{lll}b_{1} & \cdots & b_{n}\end{array}\right]$ is an $n \times n$ matrix whose columns are the basis-vectors. Since the basis-vectors are linearly independent, $P$ is invertible. Since $P$ converts from the new basis to the old one, $P^{-1}$ performs the reverse transformation.

For instance, suppose $\mathbb{R}^{3}$ has the standard basis and we have a new basis

$$
b_{1}=\left[\begin{array}{c}
28 \\
-25 \\
7
\end{array}\right], b_{2}=\left[\begin{array}{c}
8 \\
-7 \\
2
\end{array}\right], b_{3}=\left[\begin{array}{c}
3 \\
-4 \\
1
\end{array}\right]
$$

We form a matrix from these columns:

$$
P=\left[\begin{array}{ccc}
28 & 8 & 3 \\
-25 & -7 & -4 \\
7 & 2 & 1
\end{array}\right]
$$

whose determinant is verified to be 1 . The vector

$$
\left[\begin{array}{c}
1 \\
-1 \\
1
\end{array}\right]
$$

in the new basis is

$$
b_{1}-b_{2}+b_{3}=P\left[\begin{array}{c}
1 \\
-1 \\
1
\end{array}\right]=\left[\begin{array}{c}
23 \\
-36 \\
10
\end{array}\right]
$$

If we want to convert the vector

$$
\left[\begin{array}{l}
1 \\
2 \\
3
\end{array}\right]
$$

in the standard basis into the new basis, we get

$$
P^{-1}\left[\begin{array}{l}
1 \\
2 \\
3
\end{array}\right]=\left[\begin{array}{ccc}
1 & -2 & -11 \\
-3 & 7 & 37 \\
-1 & 0 & 4
\end{array}\right]\left[\begin{array}{l}
1 \\
2 \\
3
\end{array}\right]=\left[\begin{array}{c}
-36 \\
122 \\
11
\end{array}\right]
$$

and a simple calculation shows that

$$
-36 b_{1}+122 b_{2}+11 b_{3}=\left[\begin{array}{l}
1 \\
2 \\
3
\end{array}\right]
$$

For matrices, changes of basis are a bit more complicated. Suppose $V$ is an $n$-dimensional vector-space and an $n \times n$ matrix, $A$, represents a linear transformation

$$
f: V \rightarrow V
$$

with respect to some basis. If $\left\{b_{1}, \ldots, b_{n}\right\}$ is a new basis for $V$, let

$$
P=\left[b_{1}, \ldots, b_{n}\right]
$$

be the matrix whose columns are the $b_{i}$. We can compute the matrix representation of $f$ in this new basis, $\bar{A}$, via

In other words, to compute a matrix representation for $f$ in the new basis:
(1) convert to the old basis (multiplication by $P$ )
(2) act via the matrix $A$, which represents $f$ in the old basis
(3) convert the result to the new basis (multiplication by $P^{-1}$ ).

We summarize this with

THEOREM 7.2.1. If $A$ is an $n \times n$ matrix representing a linear transformation

$$
f: V \rightarrow V
$$

with respect to some basis $\left\{e_{1}, \ldots, e_{n}\right\}$ and we have a new basis $\left\{b_{1}, \ldots, b_{n}\right\}$ with

$$
P=\left[\begin{array}{lll}
b_{1} & \cdots & b_{n}
\end{array}\right]
$$

then, in the new basis, the transformation $f$ is represented by

$$
\bar{A}=P^{-1} A P
$$

## Exercises.

1. Solve the system of linear equations

$$
\begin{aligned}
2 x+3 y+z & =8 \\
4 x+7 y+5 z & =20 \\
-2 y+2 z & =0
\end{aligned}
$$

2. Solve the system

$$
\begin{array}{r}
2 x+3 y+4 z=0 \\
x-y-z=0 \\
y+2 z=0
\end{array}
$$

3. If $V$ is a 3-dimensional vector-space with a standard basis and

$$
b_{1}=\left[\begin{array}{l}
8 \\
4 \\
3
\end{array}\right], b_{2}=\left[\begin{array}{c}
-1 \\
0 \\
-1
\end{array}\right], b_{3}=\left[\begin{array}{l}
2 \\
1 \\
1
\end{array}\right]
$$

is a new basis, convert the matrix

$$
A=\left[\begin{array}{ccc}
1 & 0 & -1 \\
2 & 1 & 3 \\
-1 & 2 & 1
\end{array}\right]
$$

to the new basis.

### 7.3. Dot-products and projections

Dot-products have a great deal of geometric significance. We start with:
Definition 7.3.1. If $\mathbf{v} \in \mathbb{R}^{n}$, define $\|\mathbf{v}\|=\sqrt{\mathbf{v} \bullet \mathbf{v}}$ - the norm of $\mathbf{v}$. A unit vector $\mathbf{u} \in \mathbb{R}^{n}$ is one for which $\|\mathbf{u}\|=1$.

THEOREM 7.3.2. Let $\mathbf{x}, \mathbf{y} \in \mathbb{R}^{n}$ be two vectors with an angle $\theta$ between them. Then

$$
\begin{equation*}
\cos (\theta)=\frac{\mathbf{x} \bullet \mathbf{y}}{\|\mathbf{x}\| \cdot\|\mathbf{y}\|} \tag{7.3.1}
\end{equation*}
$$

Figure 7.3.1. Projection of a vector onto another

Proof. See theorem 6.2.66 in [40].
One immediate consequence is:
REmARK 7.3.3. Vectors $\mathbf{u}$ and $\mathbf{v}$ are perpendicular if and only if

$$
\mathbf{u} \bullet \mathbf{v}=0
$$

Definition 7.3.4. Let $\mathbf{u} \in \mathbb{R}^{n}$ be a unit vector and $\mathbf{v} \in \mathbb{R}^{n}$ be some other vector. Define the projection of $\mathbf{v}$ onto $\mathbf{u}$ via

$$
\operatorname{Proj}_{\mathbf{u}} \mathbf{v}=(\mathbf{u} \bullet \mathbf{v}) \mathbf{u}
$$

Also define

$$
\mathbf{v}_{\perp}=\mathbf{v}-\operatorname{Proj}_{\mathbf{u}} \mathbf{v}
$$

Remark. Note that $\operatorname{Proj}_{\mathbf{u}} \mathbf{v}$ is parallel to $\mathbf{u}$ with a length of $\|\mathbf{v}\| \cdot \cos \theta$, where $\theta$ is the angle between $\mathbf{u}$ and $\mathbf{v}$. Also note that

$$
\begin{aligned}
\mathbf{u} \bullet \mathbf{v}_{\perp} & =\mathbf{u} \bullet(\mathbf{v}-(\mathbf{u} \bullet \mathbf{v}) \mathbf{u}) \\
& =\mathbf{u} \bullet \mathbf{v}-(\mathbf{u} \bullet \mathbf{v}) \mathbf{u} \bullet \mathbf{u} \\
& =\mathbf{u} \bullet \mathbf{v}-\mathbf{u} \bullet \mathbf{v}=0
\end{aligned}
$$

so $\mathbf{v}_{\perp}$ is perpendicular to $\mathbf{u}$ as per remark 7.3.3.
Since $\mathbf{v}=\operatorname{Proj}_{\mathbf{u}} \mathbf{v}+\mathbf{v}_{\perp}$, we have represented $\mathbf{v}$ as a sum of a vector parallel to $\mathbf{u}$ and one perpendicular to it. See figure 7.3.1.

We can generalize projection to multiple dimensions:
Definition 7.3.5. Let $\mathbf{u}_{1}, \ldots, \mathbf{u}_{k} \in \mathbb{R}^{n}$ be a set of vectors. This set is defined to be orthonormal if

$$
\mathbf{u}_{i} \bullet \mathbf{u}_{j}= \begin{cases}1 & \text { if } i=j  \tag{7.3.2}\\ 0 & \text { otherwise }\end{cases}
$$

As with a single vector, we can define projections in this case.
DEFINITION 7.3.6. If $V$ is an inner-product space, $\mathbf{v} \in V$, and $S=$ $\left\{\mathbf{u}_{1}, \ldots, \mathbf{u}_{k}\right\}$ is an orthonormal set of vectors with $W=\operatorname{Span}(S)$, then define

$$
\operatorname{Proj}_{W} \mathbf{v}=\sum_{i=1}^{k}\left(\mathbf{u}_{i} \bullet \mathbf{v}\right) \mathbf{u}_{i}
$$

If $\mathbf{v} \notin W$, what is the relation between $\mathbf{v}$ and $\operatorname{Proj}_{W} \mathbf{v}$ ?

Proposition 7.3.7. If $S=\left\{\mathbf{u}_{1}, \ldots, \mathbf{u}_{k}\right\}$ is an orthonormal set of vectors that span $W \subset \mathbb{R}^{n}$, and $\mathbf{v}$ is any other vector, then

$$
\mathbf{v}_{\perp}=\mathbf{v}-\operatorname{Proj}_{W} \mathbf{v}
$$

has the property that $\mathbf{v}_{\perp} \bullet \mathbf{u}_{j}=0$ for all $j=1, \ldots, k$, making it perpendicular to all of $W$. It follows that $\operatorname{Proj}_{W} \mathbf{v}$ is the vector in $W$ closest to $\mathbf{v}$ in the sense that

$$
\|\mathbf{v}-\mathbf{w}\|>\left\|\mathbf{v}-\operatorname{Proj}_{W} \mathbf{v}\right\|
$$

for any $\mathbf{w} \in W$ with $\mathbf{w} \neq \operatorname{Proj}_{W} \mathbf{v}$.
PROOF. See proposition 6.2.88 in [40].
Maxima has a library called eigen that adds additional functions to the system. For instance:

```
load(" eigen ");
x:matrix ([1,2,3]);
unitvector(x);
```

results in

$$
\left(\begin{array}{lll}
\frac{1}{\sqrt{14}} & \frac{2}{\sqrt{14}} & \frac{3}{\sqrt{14}}
\end{array}\right)
$$

so it returns

$$
\frac{x}{\|x\|}
$$

## ExERCISES.

1. Compute the angle between the vectors

$$
\left[\begin{array}{l}
1 \\
2 \\
3
\end{array}\right] \text { and }\left[\begin{array}{c}
1 \\
-2 \\
0
\end{array}\right]
$$

2. Consider the unit vector

$$
\mathbf{u}=\left[\begin{array}{l}
1 / \sqrt{3} \\
1 / \sqrt{3} \\
1 / \sqrt{3}
\end{array}\right]
$$

If

$$
\mathbf{v}=\left[\begin{array}{l}
1 \\
2 \\
3
\end{array}\right]
$$

compute $\operatorname{Proj}_{\mathbf{u}} \mathbf{v}$ and $\mathbf{v}_{\perp}$. Write Maxima functions to do this.
3. Given vectors

$$
\mathbf{v}_{1}=\left[\begin{array}{l}
1 \\
2 \\
3 \\
4
\end{array}\right], \mathbf{v}_{2}=\left[\begin{array}{c}
1 \\
0 \\
-1 \\
1
\end{array}\right], \mathbf{v}_{3}=\left[\begin{array}{c}
2 \\
-1 \\
-2 \\
-1
\end{array}\right]
$$

in $\mathbb{R}^{4}$, find an orthonormal set $\left\{\mathbf{u}_{1}, \mathbf{u}_{2}, \mathbf{u}_{3}\right\}$ with

$$
\operatorname{Span}\left\{\mathbf{u}_{1}, \mathbf{u}_{2}, \mathbf{u}_{3}\right\}=\operatorname{Span}\left\{\mathbf{v}_{1}, \mathbf{v}_{2}, \mathbf{v}_{3}\right\}
$$

Hint: $\mathbf{u}_{1}=\mathbf{v}_{1} /\left\|\mathbf{v}_{1}\right\|$. Now project $\mathbf{v}_{2}$ onto $\mathbf{u}_{1}$, compute $\left(\mathbf{v}_{2}\right)_{\perp}$, and make that into a unit vector, etc. This process is called the Gram-Schmidt Algorithm. The eigen library has a gramschmidt-command that almost carries this out.
7.3.1. Linear least squares. Suppose we are given a collection of data $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{n}, y_{n}\right)\right\}$ and would like to find a function $f(x)$ such that $f\left(x_{i}\right)=y_{i}$. Or, failing this, we would like to find a function that fits this data "as closely as possible". What do we mean by this?

Least squares tries to find a function that minimizes

$$
\sum_{i=1}^{n}\left(f\left(x_{i}\right)-y_{i}\right)^{2}
$$

as in figure 7.3.2 on the next page.
We will begin with the simplest case: $f(x)=c_{1} x+c_{0}$. We get a vector

$$
D=\left[\begin{array}{c}
c_{1} x_{1}+c_{0}-y_{1} \\
c_{1} x_{2}+c_{0}-y_{2} \\
\vdots \\
c_{1} x_{t-1}+c_{0}-y_{t-1} \\
c_{1} x_{t}+c_{0}-y_{t}
\end{array}\right]=\left[\begin{array}{cc}
x_{1} & 1 \\
x_{2} & 1 \\
\vdots & \vdots \\
x_{t-1} & 1 \\
x_{t} & 1
\end{array}\right]\left[\begin{array}{l}
c_{1} \\
c_{0}
\end{array}\right]-\left[\begin{array}{c}
y_{1} \\
y_{2} \\
\vdots \\
y_{t-1} \\
y_{t}
\end{array}\right]
$$

or

$$
D=X C-Y
$$

where

$$
X=\left[\begin{array}{cc}
x_{1} & 1 \\
x_{2} & 1 \\
\vdots & \vdots \\
x_{t-1} & 1 \\
x_{t} & 1
\end{array}\right], C=\left[\begin{array}{l}
c_{1} \\
c_{0}
\end{array}\right]
$$

and

$$
Y=\left[\begin{array}{c}
y_{1} \\
y_{2} \\
\vdots \\
y_{t-1} \\
y_{t}
\end{array}\right]
$$

We want to minimize $\|D\|^{2}=D^{t} D$. We get

$$
\begin{aligned}
(X C-Y)^{t}(X C-Y) & =\left(C^{t} X^{t}-Y^{t}\right)(X C-Y) \\
& =C^{t} X^{t} X C-C^{t} X^{t} Y-Y^{t} X C+Y^{t} Y
\end{aligned}
$$

Figure 7.3.2. Least squares fit

Now we differentiate by the $c_{i}$ (i.e.form the gradient) and set it to zero, to get

$$
2 X^{t} X C-2 X^{t} Y=0
$$

since $C^{t} X^{t} Y=Y^{t} X C\left(\right.$ why $\left.?^{2}\right)$.
Our least-squares problem becomes

$$
\begin{equation*}
X^{t} X C=X^{t} Y \tag{7.3.3}
\end{equation*}
$$

This simple (i.e., degree-1) case is often used in the business world, where it's called linear regression. It shows whether random-appearing data is (on the average) trending upward or downward.

Incidentally, equation 7.3 .3 will be used in much more complex examples of least-squares fits; only the definition of $X$ will change.

Example 7.3.8. Suppose

$$
Y=\left[\begin{array}{c}
1.827619199225791 \\
0.3903692355955774 \\
0.9647810497032392 \\
0.7108801143185723 \\
0.5044777533707618
\end{array}\right]
$$

and $x_{i}=i$

$$
X=\left[\begin{array}{ll}
1 & 1 \\
2 & 1 \\
3 & 1 \\
4 & 1 \\
5 & 1
\end{array}\right]
$$

then equation 7.3.3 is

$$
\left[\begin{array}{cc}
55 & 15 \\
15 & 5
\end{array}\right]\left[\begin{array}{l}
c_{1} \\
c_{0}
\end{array}\right]=\left[\begin{array}{l}
10.86861004365476 \\
4.398127352213942
\end{array}\right]
$$

[^20]

Figure 7.3.3. Linear regression
from which we get

$$
\left[\begin{array}{l}
c_{1} \\
c_{0}
\end{array}\right]=\left[\begin{array}{c}
-0.2325772012987064 \\
1.577357074338908
\end{array}\right]
$$

or

$$
y \sim x \cdot(-0.2325772012987064)+1.577357074338908
$$

so the data is trending downwards. We can plot it with
plot2d([[discrete, [[1, y[1, 1]],[2,y[2,1]],[3,y[3,1]], [4,y[4,1]],[5,y[5,1] ] ]],
$x *(-0.2325772012987064)+1.577357074338908]$,
[x,1,5],[ style ,[points , $4,7,1],[$ lines , 2, 1]],
[legend,"Data","Trend_line"]);
to get figure 7.3.3.
Incidentally, the [style,[points ,4,7,1],[ lines ,2,1]] trailing the rest of the plot-specifications gives the respective styles of the two function-plots. These always follow the other options. The specification [points , 4,7,1] specifies that the first plot is disconnected points (the default is to connect the points with lines). The specification takes the form [points,diameter,type_of_point,color]. See table F.1.1 on page 255 in appendix $F$ on page 251 for the codes.

Now we'll look at a more complex example: finding a fourth-degree polynomial that is a "formula" for the first 10 prime numbers.

Example 7.3.9. In this case

$$
Y=\left[\begin{array}{c}
2 \\
3 \\
5 \\
7 \\
11 \\
13 \\
17 \\
19 \\
23 \\
29
\end{array}\right]
$$

and, since we're approximating these by $f(x)=c_{4} x^{4}+c_{3} x^{3}+c_{2} x^{2}+c_{1} x+$ $c_{0}$ with $x_{i}=i$ for $i=1, \ldots, 10$, we get $X_{i, j}=i^{5-j}$ and use the command

## $X: \operatorname{genmatrix}(\operatorname{lambda}([i, j], i \wedge(5-j)), 10,5)$

to get

$$
X=\left[\begin{array}{ccccc}
1 & 1 & 1 & 1 & 1 \\
16 & 8 & 4 & 2 & 1 \\
81 & 27 & 9 & 3 & 1 \\
256 & 64 & 16 & 4 & 1 \\
625 & 125 & 25 & 5 & 1 \\
1296 & 216 & 36 & 6 & 1 \\
2401 & 343 & 49 & 7 & 1 \\
4096 & 512 & 64 & 8 & 1 \\
6561 & 729 & 81 & 9 & 1 \\
10000 & 1000 & 100 & 10 & 1
\end{array}\right]
$$

so $X^{t} X$ is
$\left[\begin{array}{ccccc}167731333 & 18080425 & 1978405 & 220825 & 25333 \\ 18080425 & 1978405 & 220825 & 25333 & 3025 \\ 1978405 & 220825 & 25333 & 3025 & 385 \\ 220825 & 25333 & 3025 & 385 & 55 \\ 25333 & 3025 & 385 & 55 & 10\end{array}\right]$
and $X^{t} Y$ is
$\left[\begin{array}{c}585514 \\ 66118 \\ 7726 \\ 952 \\ 129\end{array}\right]$
and $C$ is given by

$$
\left(X^{t} X\right)^{-1}\left(X^{t} Y\right)=C=\left[\begin{array}{c}
\frac{41}{3432} \\
-\frac{147}{572} \\
\frac{6869}{3432} \\
-\frac{542}{43} \\
\frac{25}{6}
\end{array}\right]
$$

Figure 7.3.4. "Formula" for prime numbers
so that our "formula" for the prime numbers is

$$
\frac{41 \cdot x^{4}}{3432}-\frac{147 \cdot x^{3}}{572}+\frac{6869 \cdot x^{2}}{3432}-\frac{542 \cdot x}{143}+\frac{25}{6}
$$

and figure 7.3.4 shows a comparison plot.
In the most general form of linear least squares, we approximate data via a formula

$$
f(x)=\sum_{i=1}^{n} c_{i} g_{i}(x)
$$

where the $g_{j}$ are some functions (not necessarily powers of $x$ ), and $X_{i, j}=$ $g_{j}\left(x_{i}\right)$. In our examples above, the $g_{j}(x)$ were $x^{j}$.

## Exercises.

4. Find a fifth degree polynomial that least-squares approximates the first 20 prime numbers, which are

$$
2,3,5,7,11,13,17,19,23,29,31,37,41,43,47,53,59,61,67,71
$$

### 7.4. Eigenvalues and the characteristic polynomial

Suppose $V$ is a vector space and $A: V \rightarrow V$ is a linear transformation. Recall how eigenvalues and eigenvectors are defined in terms of each other

$$
\begin{equation*}
A v=\lambda v \tag{7.4.1}
\end{equation*}
$$

where we require $v \neq 0$ and $\lambda$ to be a scalar. A nonzero vector, $v$, satisfying this equation is called an eigenvector of $A$ and the value of $\lambda$ that makes this work is called the corresponding eigenvalue.

Eigenvectors and eigenvalues are defined in terms of each other, but eigenvalues are computed first.

We rewrite equation 7.4.1 on the facing page as

$$
A v=\lambda I v
$$

where $I$ is the suitable identity matrix and get

$$
(A-\lambda I) v=0
$$

This must have solutions for nonzero vectors, $v$. This can only happen if

$$
\operatorname{det}(A-\lambda I)=0
$$

Definition 7.4.1. If $A$ is an $n \times n$ matrix

$$
\operatorname{det}(\lambda I-A)=\chi_{A}(\lambda)
$$

is a degree- $n$ polynomial called the characteristic polynomial of $A$. Its roots are the eigenvalues of $A$. Maxima has a charpoly-command

Example 7.4.2. If type
b: matrix ([1,2,3,4],[5,6,7,8],[7,8,9,10],[11,12,13,14]);
to get

$$
\left[\begin{array}{cccc}
1 & 2 & 3 & 4 \\
5 & 6 & 7 & 8 \\
7 & 8 & 9 & 10 \\
11 & 12 & 13 & 14
\end{array}\right]
$$

Its characteristic polynomial is computed by the charpoly-command

```
charpoly (b,x)
```

The first parameter is the matrix, and the second is the variable to appear in the polynomial. This generally gives a messy output expression that can be simplified by the expand-command to get

$$
\chi_{b}(x)=x^{4}-30 x^{3}-64 x^{2}
$$

with roots (eigenvalues of $b$ ) that can be computed directly (i.e., without first issuing the charpoly-command) by the eigenvalues-command which has a shorter abbreviation, eivals

```
eigenvalues(b)
```

to get

$$
[[-2,32,0],[1,1,2]]
$$

These two lists give, respectively, the eigenvalues themselves, and their corresponding multiplicities. So our eigenvalues are $0,-2,32$ with multiplicities 2,1,1, respectively.

The eigenvectors are computed by the eigenvectors-command which finds the eigenvalues and then the corresponding eigenvectors ${ }^{3}$

$$
[[[-2,32,0],[1,1,2]],
$$

$$
\left[\left[\left[1, \frac{3}{11},-\frac{1}{11},-\frac{9}{11}\right]\right],\left[\left[1, \frac{7}{3}, 3, \frac{13}{3}\right]\right],[[1,0,-3,2],[0,1,-2,1]]\right]
$$

This output consists of a list of
(1) Eigenvalues and multiplicities (identical to the output of the eigenvalues-command),
(2) For each eigenvalue, a list of the corresponding eigenvectors (there might be more than one). In this example, the eigenvalue 0 has two linearly independent eigenvectors. These vectors are listed as row-vectors rather than the column-vectors used in section 7.2 on page 107.
We will try to do what was done in section 7.2 on page 107 using the matrix b. We cut and paste the eigenvectors computed earlier into a matrix

First, we type
pt: matrix $([1,3 / 11,-1 / 11,-9 / 11],[1,7 / 3,3,13 / 3]$,
[1,0,-3,2],[0,1,-2,1]);
to get

$$
\left[\begin{array}{cccc}
1 & \frac{3}{11} & -\frac{1}{11} & -\frac{9}{11} \\
1 & \frac{7}{3} & 3 & \frac{13}{3} \\
1 & 0 & -3 & 2 \\
0 & 1 & -2 & 1
\end{array}\right]
$$

Since this has row vectors rather than the column vectors we want, we use the transpose-command

```
p:transpose(pt)
```

to get

$$
p=\left[\begin{array}{cccc}
1 & 1 & 1 & 0 \\
\frac{3}{11} & \frac{7}{3} & 0 & 1 \\
-\frac{1}{11} & 3 & -3 & -2 \\
-\frac{9}{11} & \frac{13}{3} & 2 & 1
\end{array}\right]
$$

Now we are ready to play!
$\mathrm{d}:\left(\mathrm{p}^{\wedge \wedge}-1\right) \cdot \mathrm{b} \cdot \mathrm{p}$
gives

$$
d=\left[\begin{array}{cccc}
-2 & 0 & 0 & 0 \\
0 & 32 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{array}\right]
$$

so the matrix $b$ simply multiplies the first basis-vector by -2 , the second by 32 , and kills the remaining basis vectors.

[^21]The expression

$$
p \cdot d \cdot\left(p^{\wedge \wedge}-1\right)
$$

recovers our original b-matrix.
Since diagonal matrices behave like scalars

$$
d^{n}=\left[\begin{array}{cccc}
(-2)^{n} & 0 & 0 & 0 \\
0 & 32^{n} & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{array}\right]
$$

for $n>0$. We can get a closed form of the $n^{\text {th }}$ power of $\mathfrak{b}$ by writing
p. $\mathrm{d}^{\wedge} \mathrm{n} \cdot\left(\mathrm{p}^{\wedge \wedge}-1\right)$
(here, we're using the fact that a single carat simply raises each element of the matrix to a power) to get a closed form expression for $b^{n}$ :

$$
\left[\begin{array}{cccc}
\frac{11 \cdot(-2)^{n}}{17}+\frac{39 \cdot 32^{n-1}}{17} & \frac{45 \cdot 32^{n-1}}{17^{2}}-\frac{11 \cdot(-2)^{n-1}}{17} & 3 \cdot 32^{n-1} & \frac{57 \cdot 37 n^{n-1}}{17}+\frac{11 \cdot(-2)^{n-1}}{17} \\
\frac{3 \cdot(-2)^{n}}{17}+\frac{91 \cdot 3^{n-1}}{17} & \frac{105 \cdot 3 n^{n-1}}{17}-\frac{3 \cdot(-2)^{n-1}}{17} & 7 \cdot 32^{n-1} & \frac{133 \cdot 32^{n-1}}{17}+\frac{3 \cdot(-2)^{n-1}}{17} \\
\frac{117 \cdot 32^{n-1}}{17}-\frac{(-2)^{n}}{17} & \frac{135 \cdot 32^{n-1}}{17}+\frac{(-2)^{n-1}}{17} & 9 \cdot 32^{n-1} & \frac{171 \cdot 32^{n-1}}{17}-\frac{(-2)^{n-1}}{17} \\
\frac{169 \cdot 37^{n-1}}{17}-\frac{9 \cdot(-2)^{n}}{17} & \frac{195 \cdot 3 n^{n-1}}{17}+\frac{9 \cdot(-2)^{n-1}}{17} & 13 \cdot 32^{n-1} & \frac{247 \cdot 32^{n-1}}{17}-\frac{9 \cdot(-2)^{n-1}}{17}
\end{array}\right]
$$

which we can ratsimp to

$$
\left[\begin{array}{cccc}
\frac{39 \cdot 32^{n}-11 \cdot(-2)^{n+5}}{544} & \frac{11 \cdot(-2)^{n+4}+45 \cdot 32^{n}}{544} & 3 \cdot 32^{n-1} & \frac{57 \cdot 32^{n}-11 \cdot(-2)^{n+4}}{544} \\
\frac{91 \cdot 32^{n}-3 \cdot(-2)^{n+5}}{544} & \frac{3 \cdot(-2)^{n+4}+105 \cdot 32^{n}}{544} & 7 \cdot 32^{n-1} & \frac{133 \cdot 32^{n}-3 \cdot(-2)^{n+4}}{544} \\
\frac{(-2)^{n+5}+117 \cdot 32^{n}}{544} & \frac{135 \cdot 32^{n}-(-2)^{n+4}}{544} & 9 \cdot 32^{n-1} & \frac{(-2)^{n+4}+171 \cdot 32^{n}}{544} \\
\frac{9 \cdot(-2)^{n+5}+169 \cdot 32^{n}}{544} & \frac{195 \cdot 32^{n}-9 \cdot(-2)^{n+4}}{544} & 13 \cdot 32^{n-1} & \frac{9 \cdot(-2)^{n+4}+247 \cdot 32^{n}}{544}
\end{array}\right]
$$

The reader might wonder why we are interested in eigenvalues and eigenvectors. The answer is simple:

Equation 7.4 .1 on page 116 shows that $A$ behaves like a scalar when it acts on an eigenvector.
If we could find a basis for our vector space of eigenvectors, $A$ would become a diagonal matrix in that basis - because it merely multiplies each basisvector by a scalar.

EXAMPLE 7.4.3. It is also possible for eigenvectors to not span a vector space. Consider the matrix

$$
B=\left[\begin{array}{ll}
1 & 1 \\
0 & 1
\end{array}\right]
$$

This has a single eigenvalue, $\lambda=1$, and its eigenspace is one-dimensional, spanned by

$$
\left[\begin{array}{l}
1 \\
0
\end{array}\right]
$$

so there doesn't exist a basis of $\mathbb{R}^{2}$ of eigenvectors of $B$. All matrices (even those like $B$ above) have a standardized form that is "almost" diagonal called Jordan Canonical Form.

We conclude this section with (see [40, chapter 6] for a proof):
THEOREM 7.4.4 (Cayley-Hamilton). If $A$ is an $n \times n$ matrix with characteristic polynomial

$$
\chi_{A}(\lambda)
$$

then $\chi_{A}(A)=0$.
REMARK. In other words, every matrix "satisfies" its characteristic polynomial.

The Cayley-Hamilton Theorem can be useful in computing powers of a matrix. For instance, if the characteristic polynomial of a matrix, $A$, is $\lambda^{2}-5 \lambda+3$, we know that

$$
A^{2}=5 A-3 I
$$

so all integer powers of $A$ will be linear combinations of $A$ and $I$. Since $A$ is invertible

$$
A=5 I-3 A^{-1}
$$

or

$$
A^{-1}=\frac{1}{3}(5 I-A)
$$

This can also be used to calculate other functions of a matrix. If

$$
f(X)
$$

is a high-order polynomial or even an infinite series, write

$$
f(X)=\chi_{A}(X) \cdot g(X)+r(X)
$$

where $r(X)$ is the remainder with $\operatorname{deg} r(X)<\operatorname{deg} \chi_{A}(X)$ and

$$
f(A)=r(A)
$$

This also one of the reasons we have a charpoly-command in Maxima: sometimes the characteristic polynomial is useful in its own right and not only as a way to compute eigenvalues.

Sir William Rowan Hamilton, (1805-1865) was an Irish physicist, astronomer, and mathematician who made major contributions to mathematical physics (some had applications to quantum mechanics), optics, and algebra. He invented quaternions, a generalization of the complex numbers (see [40, chapter 9]).

## Exercises.

1. If

$$
A=\left[\begin{array}{ccc}
-9 & 2 & -3 \\
8 & 1 & 2 \\
44 & -8 & 14
\end{array}\right]
$$

compute a closed form expression for $A^{n}$.
2. Compute a square root of the matrix, $A$.
3. Generate a $10 \times 10$ matrix whose entries are the row minus the column. Find its eigenvalues.
4. Consider two sequences recursively defined by

$$
\begin{aligned}
a_{n+1} & =2 a_{n}+2 b_{n} \\
b_{n+1} & =k a_{n}+7 b_{n}
\end{aligned}
$$

with $a_{0}=1$ and $b_{0}=0$. Hows do you choose the real number, $k$, so that

$$
\lim _{n \rightarrow \infty} \frac{a_{n+1}}{a_{n}}=5
$$

? In this case, find

$$
\lim _{n \rightarrow \infty} \frac{b_{n+1}}{a_{n}}
$$

7.4.1. Population dynamics. We will use linear algebra to study agedistributions of populations. Suppose we have a population of organisms that has a maximum lifespan of $k$ years (or units of time that might not be years). Let $n_{i} \geq 0$ denote the number of creatures alive at year $i$, let $0 \leq s_{i} \leq 1$ be the fraction of creatures that survive from year $i$ to year $i+1$, and let $0 \leq f_{i}$ be the average number of offspring creatures at age $i$ have.

We have what is called the Leslie Matrix, describing the dynamics of this system (see [28])

$$
\left[\begin{array}{c}
n_{0} \\
\vdots \\
n_{k-1}
\end{array}\right]_{t+1}=\left[\begin{array}{ccccc}
f_{0} & \cdots & \cdots & \cdots & f_{k-1} \\
s_{0} & 0 & \cdots & \ddots & 0 \\
0 & s_{1} & 0 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & s_{k-2} & 0
\end{array}\right]\left[\begin{array}{c}
n_{0} \\
\vdots \\
n_{k-1}
\end{array}\right]_{t}
$$

or

$$
\mathbf{N}_{t+1}=\mathbf{T} \mathbf{N}_{t}
$$

We are interested in
(1) Ratios between the various age groups, when the population stabilizes,
(2) How fast it grows after this stabilization.

The population's age-ratios will have stabilized when

$$
\mathbf{N}_{t+1}=\lambda \mathbf{N}_{t}
$$

for some scalar, $\lambda$ - i.e., when $\mathbf{N}_{t}$ is an eigenvector of $\mathbf{T}$. The corresponding eigenvalue, $\lambda$, shows how rapidly the overall population grows or shrinks.

Let's do an example.
Example 7.4.5. A study of tribbles on planet ceti-alpha-6 shows that their Leslie Matrix is

$$
T=\left[\begin{array}{ccccc}
0 & 1 & 3 & 1 & 0 \\
0.9 & 0 & 0 & 0 & 0 \\
0 & 0.6 & 0 & 0 & 0 \\
0 & 0 & 0.5 & 0 & 0 \\
0 & 0 & 0 & 0.3 & 0
\end{array}\right]
$$

We dutifully type

```
eigenvalues(T)
```

and get a lengthy string of square roots and other radicals. Typing bfloat(\%) gives

```
[[(-7.693353249757961b-1 %i ) -6.381300992460435b-1,
7.693353249757961b-1 %i - 6.381300992460435b-1,
-1.84947536902627b-1, 1.461207735394714b0, 0.0b0],
[1.0b0, 1.0b0, 1.0b0, 1.0b0, 1.0b0]]
```

If we ask for eigenvectors, Maxima pauses for a long time and finally reports that there aren't any!

What has gone wrong?
Consider the eigenvalue 1.461207735394714 .
The nullspace of

```
U:T-1.461207735394714*ident (5)
```

should be the eigenvector associated with this eigenvalue. If we type

```
nullspace(U)
```

Maxima comes back with

## [?]

What has happened? Is Maxima broken? For U to have a nullspace, its determinant must vanish. The command

```
determinant(U)
```

gives

## $1.110223024625157 \cdot 10^{-16}$

which is very small but not zero. This illustrates the strength and weakness of Maxima: it insists on exact arithmetic. The number 1.461207735394714 is very close to an eigenvalue but not exactly equal to one ${ }^{4}$. We need a linear algebra system that can work with non-exact arithmetic.

Luckily, there's a library of linear algebra routines that will treat numbers like that in equation 7.4 .2 as zero. We load it with the command
load("lapack")
One command that is available is

[^22]```
dgeev(t,u,f);
```

where $t$ is a square matrix of real numbers and $u$ and $f$ are truth-values (they default to 'false' if omitted). The output is the set of eigenvalues and their multiplicities. If $u$ is not false, it outputs an array of right-eigenvectors, i.e.

$$
t v=\lambda v
$$

If f is not false, it also outputs left eigenvectors

$$
v^{H} t=\lambda v^{H}
$$

where $v^{H}$ is the conjugate-transpose of $v$. All we want are right eigenvectors, so we type

```
dgeev(t,true,false);
```

and get a list of eigenvalues

$$
\begin{gathered}
0 \\
1.461207735394714 \\
0.7693353249757966 \cdot i-0.6381300992460446 \\
-0.7693353249757966 \cdot i-0.6381300992460446 \\
-0.1849475369026271
\end{gathered}
$$

and a huge $5 \times 5$ array whose columns are corresponding eigenvectors.
The only positive real eigenvalue is 1.461207735394714 , so we pick that. Its corresponding eigenvector is the second column of the eigenvector-matrix:

$$
\left[\begin{array}{c}
0.8301290523484829 \\
0.5113004325232492 \\
0.2099497915887227 \\
0.07184118537806998 \\
0.01474968622965787
\end{array}\right]
$$

We normalize this to sum up to 1 (how is this done?) and get

$$
\left[\begin{array}{c}
0.5068035295561001  \tag{7.4.3}\\
0.3121549151101902 \\
0.1281768119134142 \\
0.04385988686228456 \\
0.009004856558010907
\end{array}\right]
$$

so this is the population-distribution of tribbles when it stabilizes.
In each time unit, the population is multiplied by the eigenvalue 1.461207735394714 , so tribbles multiply rapidly ${ }^{5}$.

In general, there's nothing wrong with Maxima's exact computations (and a lot that is right). In dealing with approximate data and purely numeric computations, the lapack library may be advantageous.

That library contains a number of other routines:

[^23]dgeqrf(A) Computes the QR decomposition of the matrix $\mathrm{A}: A=Q R$, where $Q$ is a square orthonormal ${ }^{6}$ matrix with the same number of rows as $A$ and $R$ is an upper-triangular matrix.
$\operatorname{dgesv}(\mathrm{A}, \mathrm{b})$ Solves the linear algebra problem $A x=b$, where $A$ and $b$ are made up of real, floating point numbers.
dgemm(A,B) dgemm (A, B, options) Compute the product of two matrices and optionally add the product to a third matrix.

In the simplest form, $\operatorname{dgemm}(\mathrm{A}, \mathrm{B})$ computes the product of the two real matrices, A and B.

In the second form, dgemm computes the alpha * A * B + beta * C where $\mathrm{A}, \mathrm{B}, \mathrm{C}$ are real matrices of the appropriate sizes and alpha and beta are real numbers. Optionally, A and/or B can be transposed before computing the product. The extra parameters are specified by optional keyword arguments: The keyword arguments are optional and may be specified in any order. They all take the form key=val. The keyword arguments are:
C The matrix $C$ that should be added. The default is false, which means no matrix is added.
alpha The product of A and B is multiplied by this value. The default is 1 .
beta If a matrix $C$ is given, this value multiplies $C$ before it is added. The default value is 0 , which implies that C is not added, even if C is given. Hence, be sure to specify a non-zero value for beta.
transpose_a If true, the transpose of A is used instead of A for the product. The default is false.
transpose_b If true, the transpose of B is used instead of B for the product. The default is false.
zgeev(A) zgeev (A, right_p, left_p) Like dgeev, but the matrix A is complex.
zheev(A) zheev(A, eigvec_p) Like zgeev, but the matrix A is assumed to be a square complex Hermitian matrix. If eigvec_p is true, then the eigenvectors of the matrix are also computed.

No check is made that the matrix A is, in fact, Hermitian.
A list of two items is returned, as in dgeev: a list of eigenvalues, and false or the matrix of the eigenvectors.

## EXERCISES.

5. Write a function that takes a vector (representing the initial number of tribbles available in each age-group) and an integer $n$ that returns the population-distribution of tribbles in time-unit $n$. How fast does this converge to the stable distribution in equation 7.4 .3 on the previous page? Is there an initial distribution that doesn't converge to the stable distribution?

[^24]

Figure 7.4.1. A sample web
7.4.2. The 25-billion-dollar eigenvector ${ }^{7}$. Although several search engines predated Google (Yahoo, etc.), Google distinguished itself by the quality of its results. It seemed to find the most relevant web pages so one did not have to wade through countless links to find interesting information. This largely due to Google's Page rank algorithm, which manages to pick out these web pages.

This raises a question:
How can one determine relevance in any search? Doesn't it depend on the subject matter?
Google solved this problem by counting the number of pages that link to a given web page, i.e. the number of back-links the page possesses: the more back-links, the more people are interested in the page - regardless of the subject-matter. See the groundbreaking paper [6].

Consider the web in figure 7.4.1.
If $x_{i}$ is the importance of node $i$, then back-link-counts gives us
$\triangleright x_{1}=x_{9}=x_{10}=0$
$\triangleright x_{2}=x_{4}=x_{5}=x_{6}=x_{7}=1$
$\triangleright x_{8}=4$
$\triangleright x_{3}=6$
so the most important node is 3 .

[^25]On the other hand, we should take into account the importance of a page that links to another so we get equations like

$$
\begin{aligned}
& \triangleright x_{3}=x_{2}+x_{4}+x_{9}+x_{10} \\
& \triangleright x_{2}=x_{1}, x_{4}=x_{1} \\
& \triangleright \text { etc. }
\end{aligned}
$$

Another consideration is the number of outgoing links a page has: the more of these, the greater the page's influence on the whole process. We remedy that by normalizing the effect of the links: each link of a page that has $n$ outgoing links gets a weight of $1 / n$. Every web page has the same effect on the final result.

If page $k$ has $n_{k}$ outgoing links, then the equations above are rewritten as

$$
\begin{equation*}
x_{i}=\sum_{k \in B_{i}} \frac{x_{k}}{n_{k}} \tag{7.4.4}
\end{equation*}
$$

where $B_{i}$ is the set of back-links of page $i$. We can enter this data into an $n \times n$ matrix, $L$, called the link matrix, where

$$
L_{i, j}= \begin{cases}0 & \text { if there's no link from page } j \text { to page } i \\ 1 / n_{j} & \text { if there's a link from page } j \text { to page } i\end{cases}
$$

For instance, the graph in figure 7.4.1 on the previous page has a link matrix of

$$
L=\left[\begin{array}{cccccccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 & .5 & 0 & 0  \tag{7.4.5}\\
.25 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
.25 & .5 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
.25 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & .5 & 0 & 0 \\
0 & 0 & 0 & 0 & .5 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & .5 & 0 & 0 & 0 & 0 & 0 \\
.25 & .5 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{array}\right]
$$

and if $\mathbf{X}$ is a $10 \times 1$ matrix (i.e., vector) of the importance-values, then

$$
L \mathbf{X}=\mathbf{X}
$$

i.e., plugging the values into the right side of equations 7.4 .4 should give the importance-values back. In other words, $X$ is an eigenvector of $L$ with eigenvalue 1 . The matrix, $L$ has two properties
(1) All of its entries are nonnegative,
(2) Its columns all sum up to 1 .

These properties make it what is called a column-stochastic matrix. This turns out to guarantee that it has 1 as an eigenvalue.

Typing
eigenvalues (L) ;
gives an incredibly messy answer, but shows that $L$ does have an eigenvalue of 1 . Typing

```
eigenvectors(L);
```

causes Maxima to complain that it cannot compute the first four eigenvectors ${ }^{8}$, but the one corresponding to the eigenvalue 1 is

$$
[0,0,0,1,0,0,0,0,0,0]^{t}
$$

showing that the most important page is number 4 , a surprising result!
If we
load("lapack")
and type

```
dgeev(L,true,false);
```

we get a similar numeric result.
In the example above, the eigenspace corresponding to the eigenvalue 1 was one-dimensional, so we got a unique ranking. Suppose we had $r$ disjoint sub-webs of our original web. In this case, our link-matrix would look like

$$
L=\left[\begin{array}{ccc}
\mathbf{D}_{1} & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \mathbf{D}_{r}
\end{array}\right]
$$

where $\mathbf{D}_{i}$ is the link-matrix of the $i^{\text {th }}$ sub-web. Each of these sub-webs will have a ranking independent of the others so that the eigenspace of $L$ corresponding to the eigenvalue 1 will be $r$-dimensional. If we compute this eigenspace we get $r$ vectors that span it, not necessarily the rank vectors of the sub-webs (which will be some linear combination of those $r$ vectors).

Google solved this problem by "slightly connecting" the sub-webs together. Let the total number of web-pages be $n$ and let $S$ be an $n \times n$ matrices whose entries are all $1 / n$. Then form

$$
\begin{equation*}
M=(1-c) L+c S \tag{7.4.6}
\end{equation*}
$$

where $c$ is some small number. Google initially used $c=.15$. The resulting $M$ matrix will still be column-stochastic but will have a one-dimensional eigenspace for the eigenvalue 1.

Although Google has enormous computing power at its disposal, it is certainly unable to process billion-by-billion matrices in the usual fashion (in finding eigenvalues and eigenvectors, for instance). Google uses the power method to compute the eigenvector corresponding to the eigenvalue 1.

Very crudely (!), the idea is

$$
M M^{\infty} \mathbf{X}=M^{\infty+1} \mathbf{X}=M^{\infty} \mathbf{X}
$$

[^26]where $\mathbf{X}$ is a "typical" nonzero vector. We start with some nonzero vector $\boldsymbol{X}_{0}$ and define
$$
\mathbf{X}_{k+1}=M \mathbf{X}_{k}
$$
and hope this converges to the actual eigenvector, $\overline{\mathbf{X}}$ as $k \rightarrow \infty$. We also normalize $\mathbf{X}_{k+1}$ so it doesn't grow or shrink in this process: If $\mathbf{v}$ is an $n$ dimensional vector with components $\left\{v_{i}\right\}$, define
$$
\|\mathbf{v}\|_{1}=\sum_{i=1}^{n}\left|v_{i}\right|
$$
and our iterative process is
\[

$$
\begin{equation*}
\mathbf{X}_{k+1}=\frac{M \mathbf{X}_{k}}{\left\|M \mathbf{X}_{k}\right\|_{1}} \tag{7.4.7}
\end{equation*}
$$

\]

See [43] for an analysis of when this type of process converges.
Here's an interpretation of taking powers of the original link matrix, $L$ :

$$
\left(L^{2}\right)_{i, j}>0
$$

if and only if there a path of length $\leq 2$ that connects node $j$ to node $i$. Why?

$$
\left(L^{2}\right)_{i, j}=\sum_{k=1}^{n} L_{i, k} L_{k, j}
$$

and this is $>0$ if both $L_{i, k}$ and $L_{k, j}$ are $>0$ for at least one value of $k$. A simple induction shows that

$$
\left(L^{r}\right)_{i, j}>0
$$

if and only if there's a path of length $\leq r$ connecting $j$ to $i$. So:
Taking powers of the $L$-matrix is similar to randomly surfing the web and counting how many times we reach each page. The more often we reach a page, the more important that page is. The initial vector $\mathbf{X}_{0}$ represents the starting position of this random walk.

## ExERCISES.

6. Write a Maxima function to implement the iteration used in the power method (equation 7.4.7). Test it using the link matrix, $L$, in equation 7.4.5 on page 126 converted to $M$ via equation 7.4.6 on the previous page with $c=.15$. Does it converge?

Compare this with the actual eigenvector, computed via dgeev.

### 7.5. Functions of matrices

If $M$ is a matrix, we can plug it into power series to compute functions like $e^{M}$ or $\sin M$ and $\cos M$.

If a matrix can be diagonalized, it's easy to compute functions like these. Consider the matrix

$$
E=\left[\begin{array}{cccc}
1 & 2 & 3 & 4 \\
5 & 6 & 7 & 8 \\
7 & 8 & 9 & 10 \\
11 & 12 & 13 & 14
\end{array}\right]
$$

from section 7.4 on page 116. We know that $E$ can be diagonalized to

$$
d=\left[\begin{array}{cccc}
-2 & 0 & 0 & 0 \\
0 & 32 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{array}\right]
$$

where $E=p . d .\left(p^{\wedge \wedge-1) ~ a n d ~}\right.$

$$
p=\left[\begin{array}{cccc}
1 & 1 & 1 & 0 \\
\frac{3}{11} & \frac{7}{3} & 0 & 1 \\
-\frac{1}{11} & 3 & -3 & -2 \\
-\frac{9}{11} & \frac{13}{3} & 2 & 1
\end{array}\right]
$$

Then

$$
\begin{gathered}
e^{d}=\left[\begin{array}{cccc}
e^{-2} & 0 & 0 & 0 \\
0 & e^{32} & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{array}\right] \\
e^{E}=p \cdot e^{d} \cdot p^{\wedge \wedge-1}
\end{gathered}
$$

giving

The exponential is so important that Maxima has a command to produce it, namely the matrixexp-command.

Its format is

```
matrixexp(thematrix,optional scalar multiplier);
```

If the scalar multiplier is omitted, it is assumed to be 1 . The reason for this multiplier will become clear momentarily.

Suppose we have a system of differential equations

$$
\begin{aligned}
& \frac{d x}{d t}=3 x-4 y \\
& \frac{d y}{d t}=2 x-y
\end{aligned}
$$

written more compactly as

$$
\frac{d v}{d t}=M v
$$

where

$$
v=\left[\begin{array}{l}
x \\
y
\end{array}\right]
$$

and

$$
M=\left[\begin{array}{ll}
3 & -4 \\
2 & -1
\end{array}\right]
$$

The well-known solution is

$$
\left[\begin{array}{l}
x \\
y
\end{array}\right]=e^{t \cdot M} \cdot\left[\begin{array}{l}
x(0) \\
y(0)
\end{array}\right]
$$

If you differentiate the power-series for $e^{t \cdot M}$ with respect to $t$, you get $M e^{t \cdot M}$. Typing

```
m: matrix ([3, -4],[2,-1])
matrixexp (m,t);
```

results in

Since the original problem didn't include any imaginary numbers, it's safe to assume we should convert these imaginary exponentials to sines and cosines.

The demoivre-command replaces all occurrences of $e^{i x}$ by $\cos (x)+$ $i \sin (x)$ :

```
demoivre(%)
```

but applying it as once might not be the best approach. A few experimental sequences of commands shows that

```
expand(%);
demoivre(%);
trigsimp(%);
```

provides the simplest result:

$$
\left[\begin{array}{cc}
\% e^{t} \cdot \sin (2 \cdot t)+\% e^{t} \cdot \cos (2 \cdot t) & -2 \cdot \% e^{t} \cdot \sin (2 \cdot t) \\
\% e^{t} \cdot \sin (2 \cdot t) & \% e^{t} \cdot \cos (2 \cdot t)-\% e^{t} \cdot \sin (2 \cdot t)
\end{array}\right]
$$

Here, the trigsimp-command can be used to simplify some trigonometric expressions. Alternatively, we could have applied the realpart-command to the matrix.

Other trigonometric commands are trigreduce and trigrat.
Note: the opposite of demoivre is the exponentialize-command which converts trigonometric functions into their exponential form.

## EXERCISES.

1. Find the sine and cosine of the matrix

$$
\left[\begin{array}{ll}
1 & 2 \\
3 & 4
\end{array}\right]
$$

Hint: use De Moivre's formula and use the realpart and imagpart commands.
2. If $x$ is a scalar variable, compute

$$
x\left[\begin{array}{ll}
1 & 2 \\
3 & 4
\end{array}\right]
$$

7.5.1. Affine groups and motions in space. In this section we will analyze groups that originate in geometry - groups of symmetries and motions.

To understand the geometry of $\mathbb{R}^{n}$, it is not enough to simply be able to rotate space about a fixed point (namely, the origin - which matrixoperations do). We must also be able to move objects through space, to displace them. This leads to the affine groups.

Regard $\mathbb{R}^{n}$ as the plane $x_{n+1}=1$ in $\mathbb{R}^{n+1}$. An $(n+1) \times(n+1)$ matrix of the form

$$
D\left(a_{1}, \ldots, a_{n}\right)=\left[\begin{array}{ccccc}
1 & 0 & \cdots & 0 & a_{1}  \tag{7.5.1}\\
0 & 1 & \ddots & \vdots & \vdots \\
\vdots & \ddots & \ddots & 0 & a_{n-1} \\
\vdots & \ddots & 0 & 1 & a_{n} \\
0 & \cdots & \cdots & 0 & 1
\end{array}\right]
$$

preserves this imbedded copy of $\mathbb{R}^{n}$ and displaces it so that the origin is moved to the point $\left(a_{1}, \ldots, a_{n}\right)$. A simple calculation shows that

$$
D\left(a_{1}, \ldots, a_{n}\right) \cdot D\left(b_{1}, \ldots, b_{n}\right)=D\left(a_{1}+b_{1}, \ldots, a_{n}+b_{n}\right)
$$

which implies that the matrices of the form $D\left(a_{1}, \ldots, a_{n}\right) \in \operatorname{GL}(n, \mathbb{R})$ form a subgroup, $S \subset G L(n+1, \mathbb{R})$ isomorphic to $\mathbb{R}^{n}$.

Definition 7.5.1. If $n>0$ is an integer and $G \subset G L(n, \mathbb{F})$ is a subgroup, the subgroup of $\mathrm{GL}(n+1, \mathbb{F})$ generated by matrices

$$
M=\left[\begin{array}{ll}
g & 0 \\
0 & 1
\end{array}\right]
$$

for $g \in G$ and matrices of the form $D\left(a_{1}, \ldots, a_{n}\right)$ with the $a_{i} \in \mathbb{F}$ is called the affine group associated to $G$ and denoted $\operatorname{Aff}(G)$.

Recall that
DEfinition 7.5.2. An $n \times n$ matrix, $A$ will be called orthogonal if

$$
A A^{t}=I
$$

REMARK. Recall the properties of orthogonal matrices (as always, see [40])
(1) They form a group, $O(n)$,called the orthogonal group,
(2) if $A$ is an orthogonal matrix, then $\operatorname{det} A= \pm 1$. If $\operatorname{det} A=1, A$ will be called special orthogonal.
(3) An orthogonal matrix, $A$, as a linear transformation $A: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ preserves angles between vectors and lengths of vectors. In other words, the matrices in $O(n)$ represent rotations and reflections. The group $\mathrm{SO}(n, \mathbb{R})$ eliminates the reflections.

Recall that if we want to represent rotation in $\mathbb{R}^{2}$ via an angle of $\theta$ in the counterclockwise direction, we can use a matrix

$$
\left[\begin{array}{cc}
\cos (\theta) & -\sin (\theta) \\
\sin (\theta) & \cos (\theta)
\end{array}\right]: \mathbb{R}^{2} \rightarrow \mathbb{R}^{2}
$$

Regard $\mathbb{R}^{2}$ as the subspace, $z=1$, of $\mathbb{R}^{3}$. The linear transformation

$$
f=\left[\begin{array}{ccc}
\cos (\theta) & -\sin (\theta) & a  \tag{7.5.2}\\
\sin (\theta) & \cos (\theta) & b \\
0 & 0 & 1
\end{array}\right]: \mathbb{R}^{3} \rightarrow \mathbb{R}^{3}
$$

in $\operatorname{Aff}(\mathrm{SO}(2, \mathbb{R}))$ sends

$$
\left[\begin{array}{l}
x \\
y \\
1
\end{array}\right] \in \mathbb{R}^{2} \subset \mathbb{R}^{3}
$$

to

$$
\left[\begin{array}{c}
x \cos (\theta)-y \sin (\theta)+a \\
x \sin (\theta)+y \cos (\theta)+b \\
1
\end{array}\right] \in \mathbb{R}^{2} \subset \mathbb{R}^{3}
$$

and represents
(1) rotation by $\theta$ (in a counterclockwise direction), followed by
(2) displacement by $(a, b)$.

Affine group-actions are used heavily in computer graphics: creating a scene in $\mathbb{R}^{3}$ is done by creating objects at the origin of $\mathbb{R}^{3} \subset \mathbb{R}^{4}$ and moving them into position (and rotating them) via linear transformations in $\mathbb{R}^{4}$. A high-end (and not so high end) computer graphics card performs millions of affine group-operations per second.

### 7.6. Linear Programming

7.6.1. Introduction. We will discuss an application of linear algebra to a widely used industrial function.

Here's an example of a linear programming problem:
EXAMPLE 7.6.1. A calculator company produces a scientific calculator and a graphing calculator. Long-term projections indicate an expected demand of at least 100 scientific and 80 graphing calculators each day.
(1) Because of limitations on production capacity, no more than 200 scientific and 170 graphing calculators can be made daily.

Figure 7.6.1. Feasible region
(2) To satisfy a shipping contract, a total of at least 200 calculators much be shipped each day.
(3) If each scientific calculator sold results in a $\$ 2$ loss, but each graphing calculator produces a $\$ 5$ profit, how many of each type should be made daily to maximize net profits?
Let $s$ denote the number of scientific calculators and $g$ the number of graphing calculators produced each day.

The word problem translates into a series of inequalities

$$
\begin{aligned}
s+g & \geq 200 \\
s & \leq 200 \\
g & \leq 170 \\
s & \geq 100 \\
g & \geq 80
\end{aligned}
$$

And we must maximize $P=-2 s+5 g$, which is called the objective function of the problem. The inequalities define a polygonal region with 5 vertices as in figure on the current page. Points that satisfy the inequalities are called feasible solutions, and the set of them is called the feasible region. They don't necessarily solve the problem (maximize profits) but are potential solutions.

The line on the lower right of figure on this page is the profit-line, $P=$ $-2 s+5 g=100$. It may be translated parallel to itself, and we arrive at the solution to the problem in figure on the next page, with a profit of 650.

Several things stand out:
The objective function is linear, so we can't find its extrema by setting its derivatives to 0 . To see what happens, consider the function $f(x)=2 x-1$ on the closed interval $[1,5]$. Its derivative never vanishes, but its maximum occurs at $x=5$. In greater generality, the extrema occur at critical points (where derivatives vanish) or on the boundary of the region.

FIGURE 7.6.2. Linear programming solution

Induction shows that the extrema of an objective function occur at the vertices (i.e., boundary of the boundary of the...) of the feasible region.

So we could solve linear programming problems by:
(1) Computing all the vertices, using linear algebra.
(2) Plugging the objective function into each of these vertices.

Unfortunately, an $n$-dimensional cube has $2^{n}$ vertices and other constraints could easily increase this number. This exponential complexity can overwhelm the fastest computers; some industrial problems have $n>500$.

In the mid 1940's, George Dantzig invented the simplex algorithm for solving linear programming problems. It attempts to minimize the number of vertices computed and move toward the one that solves the optimization problem.

George Bernard Dantzig (1914-2005) was an American mathematical scientist who made contributions to industrial engineering, operations research, computer science, economics, and statistics.

We will not go into the simplex method's details; the interested reader is referred to [14]. Maxima has a library implementing it invoked by

```
load("simplex")
```

It's fairly easy to use. We have a command:

```
maximize_lp (objective, conditions, [pos])
```

The optional argument [pos] is a list of variables that are assumed to be positive (putting them in this list turns out to be more efficient that simply defining them to be $>0$ in the list of conditions).

For instance, the sample problem at the beginning of this section could be solved by

```
maximize_lp \((5 * \mathrm{~g}-2 * \mathrm{~s}, \quad[\mathrm{~s}<=200, \mathrm{~s}>=100\),
    \(\mathrm{g}<=170, \mathrm{~g}>=80, \mathrm{~s}+\mathrm{g}>=200 \mathrm{l})\)
```

to produce

$$
[650,[g=170, s=100]]
$$

We also have a

```
minimize_lp (objective, conditions, [pos])
```

command whose action is self-explanatory.
For much more complex problems (where it's hard to simply give a list of inequalities), we have the command

```
linear_program (A, b, c)
```

Here:
$A$ is a matrix and $b$ and $c$ are vectors. The command computes a vector, x , that minimizes $c \cdot x$ among all the vectors with the property that $A x=b$, and $x \geq 0$.

Here's an example:

```
A: matrix([1,1,-1,0], [2,-3,0,-1], [4,-5,0,0]);
b: [1,1,6];
c: [1,-2,0,0];
linear_program(A, b, c);
```

resulting in

$$
\left[\left[\frac{13}{2}, 4, \frac{19}{2}, 0\right],-\frac{3}{2}\right]
$$

where the first list gives the vector, $x$, and the second value is the objective function at that point.

There are two error-messages that these commands give:
$\triangleright$ Problem not feasible! - in this case, the inequalities contradict each other so there are no feasible solutions. Example: $x>=2, x<=1$.
$\triangleright$ Problem not bounded! - in this case the feasible region is unbounded and the solution is infinite. Example

```
maximize_lp (x, [x>=0])
```

## EXERCISES

1. A manufacturer of ski clothing makes ski pants and ski jackets. The profit on a pair of ski pants is $\$ 3.00$ and on a jacket is $\$ 2.00$. Both pants and jackets require the work of sewing operators and cutters. There are 60 minutes of sewing operator time and 48 minutes of cutter time available. It takes 8 minutes to sew one pair of ski pants and 4 minutes to sew one jacket. Cutters take 4 minutes on pants and 8 minutes on a jacket.

Find the maximum profit and the amount of pants and jackets to maximize the profit.
2. A farmer has a field of 70 acres in which he plants potatoes and corn. The seed for potatoes costs $\$ 20 /$ acre, the seed for corn costs $\$ 60 /$ acre and the farmer has set aside $\$ 3000$ to spend on seed. The profit per acre of potatoes is $\$ 150$ and the profit for corn is $\$ 50$ an acre.

Find the optimal solution for the farmer.
7.6.2. Integer programming and "industrial strength" problems. All of the problems we have considered must be regarded as "toy" problems: The number of variables and constraints are small enough to be listed in a command. In addition, we don't have constraints that require some variables to be integers. It turns out that last consideration makes linear programming infinitely harder. The mere simplex algorithm cannot handle it.

For these problems, we need specialized software, namely 'glpk', developed (in the early 2000's) by the Department for Applied Informatics, Moscow Aviation Institute, Moscow, Russia. They used it for designing airplane and jet engines.

It has been released into the public domain (and is, therefore free software) and enhanced many times in the intervening years.
$\triangleright$ Most Linux distributions have a packaged version of it.
$\triangleright$ The original source code can be found at
https://www.gnu.org/software/glpk/
$\triangleright$ A Windows port can be found at
https://winglpk.sourceforge.net/
$\triangleright$ A Macintosh version can be found at https://ports.macports.org/port/glpk/
It implements its own (fairly simple) programming language that allows for
$\triangleright$ arrays of variables, constraints, and data
$\triangleright$ requiring some variables to be integers or even binary (0 or 1)
$\triangleright$ reading these arrays from files
The manual that is packaged with the software is almost 200 pages, but most of it is devoted to accessing glpk from a C or C++ program (so, in particular, one can do that!). It can also be accessed from python programs.

We will want to run it in a standalone mode, which is relatively simpler.
Here's a sample program in the GNU MathProg modeling language:

```
# A TRANSPORTATION PROBLEM
# This problem finds a least cost shipping schedule that meets
# requirements at markets and supplies at factories.
#
# References:
# Dantzig G B, "Linear_Programming
# Princeton University Press, Princeton, New Jersey, 1963,
# Chapter 3-3.
set I;
/* canning plants */
set J;
/* markets */
param a{i in I};
/* capacity of plant i in cases */
param b{j in J };
/* demand at market j in cases */
param d{i in I, j in J};
/* distance in thousands of miles */
param f;
/* freight in dollars per case per thousand miles */
param c{i in I, j in J} := f * d[i,j] / 1000;
/* transport cost in thousands of dollars per case */
var x{i in I, j in J} >= 0;
/* shipment quantities in cases */
minimize cost: sum{i in I, j in J} c[i,j] * x[i,j];
/* total transportation costs in thousands of dollars */
s.t. supply{i in I}: sum{j in J} x[i,j]<= a[i];
/* observe supply limit at plant i */
s.t. demand{j in J}: 亦{m{i in I} x[i,j]>= b[j];
/* satisfy demand at market j */
data;
set I := Seattle San-Diego;
set J := New-York Chicago Topeka;
```

```
param b := New-York 325
    Chicago }30
\begin{tabular}{lccc} 
param d \(:\) & New-York & Chicago & Topeka \(:=\) \\
Seattle & 2.5 & 1.7 & 1.8 \\
San-Diego & 2.5 & 1.8 & \(1.4 ;\)
\end{tabular}
param f := 90;
end ;
```

You run this (in Linux) by putting it into a file 'transp.mod' and typing

```
glpsol -m transp.mod -o output.txt
```

Normally, this only prints the whether the program succeeded and some other information. The actual results of the program (i.e., the solution to the problem) go into the file 'output.txt', which is

```
Problem: transp
Rows: 6
Columns: 6
Non-zeros: 18
Status: OPTIMAL
Objective: cost = 153.675 (MINimum)
```

Several points become clear:
(1) The program has three types of identifiers: sets, params, and vars. Elements of sets can be names or numbers and are used to index identifiers.

Examples: $\mathrm{A}=1 . .10$ (this is the set $1,2,3,4,5,6,7,8,9,10$ ), $\mathrm{B}=0 . .1$ by .1 (this is the set $0,1, .2, .3, .4,5 ., 6,7, .8, .9,1$; by is an optional keyword), Weekdays=monday tuesday wednesday thursday friday. Sets do not need to have names: $\{1,2,7\},\{\mathrm{a}, \mathrm{b}, 1 . .50\}$.
(2) The constraints are all labeled and begin with 's.t.' (meaning 'subject to', which can also be spelled out).
(3) The program is in three parts: declarations, constraints (including the objective function), and data.
The statement

```
param c{i in I, j in J} := f * d[i,j] / 1000;
```

shows how one implicitly iterates over all elements of a set without coding loop-commands (although these also exist in this language).

The statement

```
minimize cost: sum{i in I, j in J} c[i,j] * x[i,j];
```

/* total transportation costs in thousands of dollars *
defines the objective function and illustrates a command, 'sum' that combines results of iterations over sets. Such "combining commands" include' ${ }^{\text {prod', ' }}{ }^{\prime} \mathbf{m i n}^{\prime}$, and 'max'.

The difference between 'var's and 'param's is that
(1) 'param's are assumed to be given, and
(2) 'var's are assumed to be initially undefined, and glpk attempts to assign values to the 'var's that satisfy the constraints.
Although this is a "toy" program, the data section could easily have had thousands of entries and be read from a file. If data is in a separate file, it could be named transp.dat and the program would be run via

```
glpsol -m transp.mod --data transp.dat -o output.txt
```

Data could also be read in a csv file (comma-separated values, a format spreadsheets use), or a mysql database.

The following example shows how linear programming with integer variables takes a problem out of the realm of linear algebra into that of arbitrary logic and general programming.

```
/* ZEBRA, Who Owns the Zebra? */
/* Written in GNU MathProg by Andrew Makhorin <mao@mai2.rcnet.ru> */
########################################################################
# The Zebra Puzzle is a well-known logic puzzle.
    It is often called "Einstein's_Puzzle" or "Einstein's_Riddle"
    because it is said to have been invented by Albert Einstein as a boy,
    with the common claim that Einstein said "only_ _ percent_of the
    world 's}\mp@subsup{s}{\sqcup}{\prime}\mathrm{ population_can
    Lewis Carroll. However, there is no known evidence for Einstein's_or
    Carroll's
    There are several versions of this puzzle. The version below is
    quoted from the first known publication in Life International
    magazine on December 17, 1962.
    1. There are five houses.
    2. The Englishman lives in the red house.
    3. The Spaniard owns the dog.
    4. Coffee is drunk in the green house.
    5. The Ukrainian drinks tea.
    6. The green house is immediately to the right of the ivory house.
    7. The Old Gold smoker owns snails .
    8. Kools are smoked in the yellow house.
    9. Milk is drunk in the middle house
    10. The Norwegian lives in the first house.
    11. The man who smokes Chesterfields lives in the house next to the
        man with the fox.
    12. Kools are smoked in the house next to the house where the horse
        is kept.
    13. The Lucky Strike smoker drinks orange juice.
    14. The Japanese smokes Parliaments.
    15. The Norwegian lives next to the blue house.
    Now, who drinks water? Who owns the zebra?
    In the interest of clarity, it must be added that each of the five
    houses is painted a different color, and their inhabitants are of
    different national extractions, own different pets, drink different
    beverages and smoke different brands of American cigarettes. One
    other thing: In statement 6, right means your right.
# (From Wikipedia, the free encyclopedia.)

```

```
/* the Norwegian lives next to the blue house */
f15 {h in HOUSE}
    (1 - nationality[h,"Norwegian"]) +
    (if h = 1 then 0 else color[h-1,"blue"]) +
    (if h = 5 then 0 else color[h+1,"blue"]) >= 1;
solve;
printf "\n";
```

$\qquad$

``` SMOKE
``` \(\qquad\)
``` PET\n";
for {h in HOUSE}
printf "%5d", h;
    printf{c in COLOR: color[h,c]} "__%-6s", c;
    printf{n in NATIONALITY: nationality[h,n]} " %-11s", n;
    printf{d in DRINK: drink[h,d]} "-s%-12s", d;
    printf{s in SMOKE: smoke[h,s]} ""%-12s", s;
    printf{p in PET: pet[h,p]} ""%%-6s", p;
    printf "\n";
}
printf "\n";
end;
```

This program contains several new elements:
(1) the 'solve' command that tells glpk to assign values to all of the 'var's that satisfy the constraints. It appears at the end of the constraints section, where a 'maximize' or 'minimize' command might appear.
(2) the 'binary' declaration. This forces a variable to only take on the values 0 or 1 .
(3) the 'printf' statement that causes data to be printed out as the program executes, so one does not need to locate the information in the output file. The format-string is like that used in the C programming language.

## CHAPTER 8

## Calculus of Finite Differences

#### Abstract

"In the following exposition of the Calculus of Finite Differences, particular attention has been paid to the connexion of its methods with those of the Differential Calculus - a connexion which in some instances involves far more than a merely formal analogy." - George Boole, in the introduction to [5].

### 8.1. A discrete introduction to finite differences

In this chapter, we will consider a discrete analogue to differential calculus. Isaac Newton invented it at roughly the same time as he invented calculus and used it to perform exacting numerical computations.

Isaac Newton $\operatorname{FRS}^{a}(1642-1726 / 27)$ was an English polymath active as a mathematician, physicist, astronomer, alchemist, theologian, and author who was described in his time as a natural philosopher. He was a key figure in the Scientific Revolution and the Enlightenment that followed. His pioneering book Philosophix Naturalis Principia Mathematica (Mathematical Principles of Natural Philosophy), first published in 1687, consolidated many previous results and established classical mechanics. Newton also made seminal contributions to optics, and shares credit with the German mathematician Gottfried Wilhelm Leibniz for developing infinitesimal calculus, though Newton developed calculus years before Leibniz (and gave it the more appropriate name, fluxions). He is considered one of the greatest and most influential scientists in history.
${ }^{a}$ Fellow of the Royal Society

As we have seen, Maxima has built-in commands diff and integrate (among others) for ordinary calculus, while it has none for finite-difference calculus. We'll program these commands using a very powerful Maxima programming language feature called macros.

What commands do we need to implement? The most basic ones are:
DEfinition 8.1.1. If $f(x)$ is a function, define
(1) $\mathbf{E}(f)(x)=f(x+1)$
(2) $\Delta f(x)=f(x+1)-f(x)=\mathbf{E}(f)-f$ or $\Delta=\mathbf{E}-1$.
(3) $\boldsymbol{\Sigma}_{a}^{b} f(x)=\sum_{x=a}^{b} f(x)$ (we assume $a, b$, and $x$ are integers).

REMARK. The operations $\Delta$ and $\boldsymbol{\Sigma}$ are approximate inverses because of the Fundamental Theorems of finite-difference calculus:

$$
\begin{align*}
\Sigma_{a}^{b} \boldsymbol{\Delta} f(x) & =\mathbf{E}(f)(b)-f(a)  \tag{8.1.1}\\
\Delta \boldsymbol{\Sigma}_{a}^{x} f(x) & =\mathbf{E}(f)
\end{align*}
$$

Because of this, $\boldsymbol{\Sigma}$ is sometimes written as $\boldsymbol{\Delta}^{-1}$.
One breakthrough in differential calculus occurred when it was discovered that

$$
\frac{d x^{n}}{d x}=n x^{n-1}
$$

so that

$$
\int x^{n} d x=\frac{x^{n+1}}{n+1}
$$

Something similar happens in finite difference calculus with Pochhammer symbols or falling factorials:

Definition 8.1.2. If $n$ is an integer and $x$ is a real number, then the falling factorial of $x$ is defined by

$$
x_{(n)}= \begin{cases}x \cdot(x-1) \cdots(x-n+1) & \text { if } n \geq 1 \\ 1 & \text { if } n=0 \\ \frac{1}{(x+1) \cdots(x-n)} & \text { if } n<0\end{cases}
$$

REMARK. Falling factorials were initially only defined for positive values of $n$. This is easily extended by noting that

$$
\frac{x_{(n+1)}}{x_{(n)}}=x-n
$$

which implies (setting $n=0$ ) that $x_{(0)}=1$, and

$$
\begin{equation*}
x_{(-1)}=\frac{1}{x+1} \tag{8.1.2}
\end{equation*}
$$

At the end of section 12.1 on page 189 this definition is extended to arbitrary complex values of $n$.

Leo August Pochhammer (1841-1920) was a Prussian mathematician who was known for his work on special functions and introducing the Pochhammer symbol.

Proposition 8.1.3. Let $n$ be an integer and let $x \in \mathbb{C}$. Then

$$
\begin{equation*}
\Delta x_{(n)}=n \cdot x_{(n-1)} \tag{8.1.3}
\end{equation*}
$$

Since this has the same structural properties as derivatives of functions like $x^{n}$, we can prove the finite-difference version of the Taylor Series:

$$
\begin{align*}
f(x)= & f(a)+\Delta[f](a)(x-a)_{(1)}+\frac{\Delta^{2}[f](a)(x-a)_{(2)}}{2!}  \tag{8.1.4}\\
& +\frac{\Delta^{3}[f](a)(x-a)_{(3)}}{3!}+\cdots \tag{8.1.5}
\end{align*}
$$

called Gregory-Newton interpolation formula. Newton proved its validity for $f$ a polynomial.

James Gregory $\mathrm{FRS}^{a}$ (1638-1675) was a Scottish mathematician and astronomer. His surname is sometimes spelled as Gregorie, the original Scottish spelling. He described an early practical design for the reflecting telescope - the Gregorian telescope - and made advances in trigonometry, discovering infinite series representations for several trigonometric functions.
In his book Geometrix Pars Universalis (1668) Gregory gave both the first published statement and proof of the fundamental theorem of calculus (from a geometric point of view, and only for a special class of curves).
${ }^{a}$ Fellow of the Royal Society
It's not hard to see that, if $a \in \mathbb{R}$ then

$$
\Delta a^{x}=(a-1) a^{x}
$$

so that

$$
\Delta 2^{x}=2^{x}
$$

It follows that $2^{x}$ is the finite-difference version of $e^{x}$ in regular calculus.
Let $\mathbf{D}$ denote the differential operator, so

$$
(\mathbf{D} f)(x)=f^{\prime}(x)
$$

The conventional Taylor series implies that

$$
f(x+1)=f(x)+\mathbf{D} f(x) \cdot 1+\frac{\mathbf{D}^{2} f(x)}{2!} 1^{2}+\cdots
$$

or

$$
f(x+1)=\left(1+\mathbf{D}+\frac{\mathbf{D}^{2}}{2!}+\cdots\right) f(x)
$$

Since the bracketed series looks like that for $e^{x}$, we conclude

$$
\mathbf{E}=e^{\mathbf{D}}
$$

and

$$
\Delta=e^{\mathbf{D}}-1
$$

or

$$
\Delta+1=e^{\mathbf{D}}
$$

from which we conclude

$$
\begin{align*}
\mathbf{D} & =\ln (1+\Delta)  \tag{8.1.6}\\
& =\Delta-\frac{\Delta^{2}}{2}+\frac{\Delta^{3}}{3}-\frac{\Delta^{4}}{4}+\cdots
\end{align*}
$$

It looks as though we have played very fast and loose with these operators, but this equation is valid when applied to any polynomial, and many other functions. One problem is that, even when it converges, it does so very slowly.

The interested reader is referred to Boole's classic, [5], which is still very relevant today.

Incidentally, Boole is famous in his own right for boolean algebras and boolean operations used in designing modern computers.

George Boole (1815-1864) was a largely self-taught English mathematician, philosopher, and logician, most of whose short career was spent as the first professor of mathematics at Queen's College, Cork in Ireland. He worked in the fields of differential equations and algebraic logic, and is best known as the author of The Laws of Thought (1854) which contains Boolean algebra. Boolean logic is credited with laying the foundations for the Information Age, alongside the work of Claude Shannon.

Now we'll investigate Harmonic numbers

$$
H(n)=\sum_{i=1}^{n} \frac{1}{n}
$$

so $\Delta H(n)=1 /(n+1)=n_{(-1)}$ (see equation 8.1.2 on page 144).
Proposition 8.1.4. If $k \geq 1$, then

$$
\Delta^{k} H(n)(1)=(-1)^{k+1}(k-1)!n_{(-k)}(1)=\frac{(-1)^{k+1}}{k(k+1)}
$$

Proof. Induction on $k$ : If true for $k-1$, we have

$$
\Delta^{k-1} H(n)(1)=(-1)^{k}(k-1)!n_{(-k+1)}(1)
$$

and

$$
\begin{aligned}
\Delta^{k} H(n) & =\Delta \Delta^{k-1} H(n)=-(-1)^{k}(k-2)!\cdot(k-1) \cdot n_{(-k)}(1) \\
& =(-1)^{k+1}(k-1)!n_{(-k)}(1)
\end{aligned}
$$

by proposition 8.1.3 on page 144. Definition 8.1.2 on page 144 shows that

$$
(-1)^{k+1}(k-1)!n_{(-k)}(1)=\frac{(-1)^{k+1}(k-1)!}{(1+1)(1+2) \cdots(1+k)}=\frac{(-1)^{k+1}}{k(k+1)}
$$

The Gregory-Newton series for harmonic numbers is, therefore,

$$
H(x)=1+\frac{x}{2}-\frac{(x-1)_{(2)}}{6 \cdot 2!}+\cdots+\frac{(-1)^{k+1}(x-1)_{(k)}}{k(k+1) k!}+\cdots
$$

Now we implement falling factorials - and this series:

```
poch[x,n]:= block(
        [],
        if n=0 then return (1),
        if n=1 then return (x),
        poch[x,n-1]*(x-n+1)
        );
h(x):=1+\operatorname{sum}((-1)^(n+1)*\operatorname{poch}[x-1,n]/(n*(n+1)*n!),n,1,50);
```

Plotting this with the command

Figure 8.1.1. The harmonic numbers
plot2d(h(x),[x,1,20]);
gives figure 8.1.1. The lack of wild oscillations shows that the harmonic numbers lend themselves to representation by a polynomial (compare this with what happens with prime numbers in the next section!).

## EXERCISES.

1. Compute

$$
\sum_{i=0}^{n} x_{(-i)}
$$

where $i \neq 1$. How do we handle the case where $i=1$ ?
2. For $n \geq 0$ an integer, show that $x^{n}$ can be written as a linear combination of falling factorials. Hint: use induction on $n$.
3. Prove equation 8.1.3 on page 144.
4. Show that

$$
\frac{x_{(n)}}{n!}=\binom{x}{n}
$$

5. Show that equation 8.1.4 on page 144 is true for all polynomials.
6. Prove the Product Formula

$$
\begin{equation*}
\boldsymbol{\Delta}(f g)=\boldsymbol{\Delta}(f) \mathbf{E}(g)+f \mathbf{\Delta}(g) \tag{8.1.7}
\end{equation*}
$$

or

$$
\boldsymbol{\Delta}(f g)=f \boldsymbol{\Delta} g+g \boldsymbol{\Delta} f+\boldsymbol{\Delta} f \boldsymbol{\Delta} g
$$

7. Prove Summation by Parts

$$
\begin{equation*}
\boldsymbol{\Sigma}_{m}^{n} f \boldsymbol{\Delta} g=\mathbf{E}(f g)(n)-(f g)(m)-\boldsymbol{\Sigma}_{m}^{n} \mathbf{E}(g) \boldsymbol{\Delta} f \tag{8.1.8}
\end{equation*}
$$

where $\mathbf{E}(g)(x)=g(x+1)$.
8. Is there a way to make equation 8.1.6 on page 145 rigorous?
9. Find a closed-form equation for

$$
\sum_{k=0}^{n} k \cdot 2^{k}
$$

Hint: Use summation by parts.
10. Prove Euler's Formula for harmonic numbers

$$
H_{n}=\int_{0}^{1} \frac{1-t^{n}}{1-t} d t
$$

This allows us to define $H_{n}$ for $n$ not an integer. For instance

$$
H_{1 / 2}=2-2 \log (2)=0.6137056388801094 \ldots
$$

### 8.2. Functional Programming and Macros

In this section, we'll implement the operators defined in the previous section in Maxima and apply them. Ideally, these operators could be implemented in a functional programming language:

A programming language is said to be functional if functions can be treated as data-items: i.e., they can be passed to other functions as parameters or arguments, and a function can return a function as its value.

There are many functional languages today: Scheme (an interesting dialect of Lisp), Common Lisp, Python, Haskell, etc. One might wonder why Maxima doesn't simply "inherit" functional programming from Common Lisp. The problem is that Maxima was originally written for Maclisp, an early form of Lisp without functional programming.

Oddly, no volunteers have stepped up and offered to rewrite Maxima (from scratch!) in modern Lisp to implement functional programming.

In a functional language, we could write
Bdelta ( $\mathrm{f}, \mathrm{x}$ ) : = lambda ([f,x],f(x+1)-f(x))
and

## Bdelta (sin ,x)

would return

```
lambda([ sin , x], sin(x+1)-\operatorname{sin}(x))
```

## whereas Maxima actually returns

$$
\operatorname{lambda}([f, x], f(x+1)-f(x))
$$

It turns out we can "fake" features of a functional language using constructs called macros. When $f(x, y, z)$ is called, Maxima
(1) evaluates $x, y, z$
(2) jumps to the function-code and plugs those values into the body of $f$.
(3) then returns with the computed values

A macro $f(x, y, z)$ superficially resembles a function but it
(1) executes the body of the macro on $x, y, z$ and other expressions (doing something like a text-edit), inserting it into the code where it was called - i.e., no jumping and returning,
(2) then it executes the revised expression.

Here's our code for the $\Delta$-operator using a macro built in to Maxima called buildq:

```
Bdelta(f,x) := buildq([y:x, g:f],
    lambda([y],g(y+1)-g(y))
        );
```

The way this executes is:
(1) buildq edits the lambda-expression, replacing $y$ by $x$ and $g$ by f (think of it as a text-edit, although the actual algorithm is faster)
(2) then it executes it

## Bdelta (sin , x)

produces
$\operatorname{lambda}([x], \sin (x+1)-\sin (x))$
and

```
Bdelta(sin,x)(x)
```

produces

```
sin(x+1)-\operatorname{sin}(x)
```

Having implemented $\Delta$, we can try to implement $\Delta^{n}$ :

$$
\begin{aligned}
& \text { Bdeltan }(f, x, n):=\operatorname{block}([], \\
& \text { if } n=1 \text { then return }(\text { Bdelta }(f, x)), \\
& \\
& \text { Bdelta }(\text { Bdeltan }(f, x, n-1), x) \\
& ) ;
\end{aligned}
$$

For instance, the command

$$
\text { Bdeltan }(\sin , x, 3)(x)
$$

Figure 8.2.1. The Gregory-Newton series
returns

$$
\sin (x+3)-3 \sin (x+2)+3 \sin (x+1)-\sin (x)
$$

Now we'll try our hand at the Gregory-Newton series (equation 8.1.4 on page 144)

```
discrete_sin(x):=sum(
    poch[x,n]*(Bdeltan(sin , x,n)(0))/n!,
    n,1,20);
```

After doing this, we plot the result with

```
plot2d(discrete_sin(x),[x,0,10])
```

to get figure 8.2.1, which shows that the Gregory-Newton series converges for some non-polynomial functions.

Now, we will try something more ambitious: a formula for prime numbers!

Let
primes: $[2,3,5,7,11,13,17,19,23$,
$29,31,37,41,43,47,53,59,61,67$,
$71,73,79,83,89,97,101,103,107$,
$109,113,127,131,137,139,149,151,157]$
denote a bunch of primes. We turn this into a function (because our routines work with functions) via

```
prime_fun(n):= primes[n]
```

and compute a bunch of $\Delta^{\prime}$ s via
dellist: makelist(Bdeltan(prime_fun, $x, n)(1), n, 20)$;

- note that we're running this Gregory-Newton series from $a=1$ rather than 0 .

This gives

$$
\begin{aligned}
\text { dellist }: & {[1,1,-1,3,-9,23,-53,115,} \\
& -237,457,-801,1213,-1389, \\
& 445,3667,-15081,41335,
\end{aligned}
$$

FIGURE 8.2.2. Polynomial giving the first 10 primes
-95059, 195769, -370803];

Now we define the series itself

$$
\operatorname{pol}(x):=2+\operatorname{sum}(d e l l i s t[k] * \operatorname{poch}[x-1, k] / k!, k, 1,20) ;
$$

This gives a polynomial such that
(1) $\operatorname{pol}(1)=2$
(2) $\operatorname{pol}(2)=3$
(3) $\operatorname{pol}(7)=17$

Now, let's plot it!
plot2d (pol(x), $[x, 1,10])$
What happened? It looks as though prime numbers don't lend themselves to be expressed by a polynomial. While one can create a polynomial that equals these primes, it oscillates wildly between them.

If we cut out the worst oscillations, we still get figure 8.2.3 on the following page.

See chapter 13 on page 211 for a far more profound discussion of prime numbers.

## Exercises.

1. Program equation 8.1 .6 on page 145 for $\sin (x)$ and $x=0$.
2. Does the Gregory-Newton series work for all analytic functions? Hint: try expanding $\sin (\pi x)$ in a Gregory-Newton series.
3. Find a closed-form equation for $\Delta^{n} f(x)$. Hint: write $\Delta^{n}=(\mathbf{E}-1)^{n}$ and use the Binomial Theorem.

FIGURE 8.2.3. Prime polynomial plot
4. Write a non-recursive version of the

## Bdeltan

command, using the equation in exercise 3 on the previous page.

## CHAPTER 9

## Nonlinear algebra

"Cantor illustrated the concept of infinity for his students by telling them that there was once a man who had a hotel with an infinite number of rooms, and the hotel was fully occupied. Then one more guest arrived. So the owner moved the guest in room number 1 into room number 2; the guest in room number 2 into number 3; the guest in 3 into room 4, and so on. In that way room number 1 became vacant for the new guest.

What delights me about this story is that everyone involved, the guests and the owner, accept it as perfectly natural to carry out an infinite number of operations so that one guest can have peace and quiet in a room of his own. That is a great tribute to solitude."

- Smilla Qaavigaaq Jaspersen, in the novel Smilla's Sense of Snow, by Peter Høeg (see [21]).

### 9.1. Introduction

As the previous chapter made clear, complex nonlinear algebraic equations often arise in practical applications.

### 9.2. Ideals and systems of equations

Define

$$
W=\mathbb{C}\left[X_{1}, \ldots, X_{n}\right]
$$

to represent the set of all polynomials in variables $X_{1}, \ldots, X_{n}$ with complex coefficients (i.e. coefficients in C)

This mathematical structure is called a ring. More formally:
Definition 9.2.1. A ring, $R$, is a set equipped with two binary operations, denoted + and multiplication, $\cdot$, such that, for all $r_{1}, r_{2}, r_{2} \in R$,
(1) $\left(r_{1}+r_{2}\right)+r_{3}=r_{1}+\left(r_{2}+r_{3}\right)$
(2) $\left(r_{1} \cdot r_{2}\right) \cdot r_{3}=r_{1} \cdot\left(r_{2} \cdot r_{3}\right)$
(3) $r_{1} \cdot\left(r_{2}+r_{3}\right)=r_{1} \cdot r_{2}+r_{1} \cdot r_{3}$
(4) $\left(r_{1}+r_{2}\right) \cdot r_{3}=r_{1} \cdot r_{3}+r_{1} \cdot r_{3}$
(5) there exists elements $0,1 \in R$ such that $r+0=0+r=r$ and $r \cdot 1=1 \cdot r=r$ for all $r \in R$.
(6) For every $r \in R$, there exists an element $s \in R$ such that $r+s=0$. The ring $R$ will be called commutative if $r_{1} \cdot r_{2}=r_{2} \cdot r_{1}$ for all $r_{1}, r_{2} \in R$.

A division ring is one in which every nonzero element has a multiplicative inverse.

A subring $S \subset R$ is a subset of $R$ that is also a ring under the operations + and.

REMARK. We will also regard the set containing only the number 0 as a ring with $0+0=0=0 \cdot 0$ - the trivial ring (the multiplicative and additive identities are the same). When an operation is written with a ' + ' sign it is implicitly assumed to be commutative.

Example. Perhaps the simplest example of a ring is the integers, $\mathbb{Z}$. This is simple in terms of familiarity to the reader but a detailed analysis of the integers is a very deep field of mathematics in itself (number theory). Its only units are $\pm 1$, and it has no zero-divisors.

We can use the integers to construct:
EXAMPLE. If $m$ is an integer, the numbers modulo $m, \mathbb{Z}_{m}$ is a ring under addition and multiplication modulo $m$. In $\mathbb{Z}_{6}$, the elements 2 and 3 are zero-divisors because $2 \cdot 3=0 \in \mathbb{Z}_{6}$.

EXAMPLE 9.2.2. The rational numbers, $\mathbb{Q}$, are an example of a field. Other examples: the real numbers, $\mathbb{R}$, and the complex numbers, $\mathbb{C}$.

REMARK. We have seen (and worked with) many examples of rings before, $\mathbb{Z}, \mathbb{Z}_{m}, \mathbb{Q}, \mathbb{R}$, and $\mathbb{C}$. The rings $\mathbb{Q}, \mathbb{R}$, and $\mathbb{C}$ are commutative division rings - also known as fields.

Definition 9.2.3. If $R$ is a ring, rings of polynomials $R[X]$ is the ring of polynomials where addition and multiplication are defined

$$
\begin{aligned}
\left(\sum_{i=0}^{n} a_{i} X^{i}\right)+\left(\sum_{i=0}^{m} b_{i} X^{i}\right) & =\sum_{i=0}^{\max (n, m)}\left(a_{i}+b_{i}\right) X^{i} \\
\left(\sum_{i=0}^{n} a_{i} X^{i}\right)\left(\sum_{j=0}^{m} b_{j} X^{j}\right) & =\sum_{k=0}^{n+m}\left(\sum_{i+j=k} a_{i} b_{j}\right) X^{k}
\end{aligned}
$$

with $a_{i}, b_{j} \in R$ and $a_{i}=0$ if $i>n$ and $b_{i}=0$ if $i>m$.
More formally, one can define $R[X]$ as the set of infinite sequences

$$
\begin{equation*}
\left(r_{0}, \ldots, r_{i}, \ldots\right) \tag{9.2.1}
\end{equation*}
$$

with the property that all but a finite number of the $r_{i}$ vanish, and with addition defined by

$$
\left(r_{0}, \ldots, r_{i}, \ldots\right)+\left(s_{0}, \ldots, s_{i}, \ldots\right)=\left(r_{0}+s_{0}, \ldots, r_{i}+s_{i}, \ldots\right)
$$

and multiplication defined by

$$
\left(r_{0}, \ldots, r_{i}, \ldots\right)\left(s_{0}, \ldots, s_{i}, \ldots\right)=\left(t_{0}, \ldots, t_{i}, \ldots\right)
$$

with

$$
t_{n}=\sum_{\substack{i+j=n \\ i \geq 0, j \geq 0}} r_{i} s_{j}
$$

(the convolution of the lists of coefficients - see definition 5.2.1 on page 78). In this case,

$$
\sum_{i=0}^{k} r_{i} X^{i}
$$

becomes the notation for the sequence $\left(r_{0}, \ldots, r_{i}, \ldots, r_{k}, 0 \cdots\right)$.
We need one more definition:
DEFINITION 9.2.4. If $R$ is a commutative ring, an ideal is a subset closed under addition $\mathfrak{I} \subset R$ such that $x \cdot r \in \mathfrak{I}$ for all $r \in R$.
(1) An ideal, $\mathfrak{I} \subset R$ is prime if $a \cdot b \in \mathfrak{I}$ implies that $a \in \mathfrak{I}$ or $b \in \mathfrak{I}$ (or both).
(2) The ideal generated by $\alpha_{1}, \ldots, \alpha_{n} \in R$, denoted $\left(\alpha_{1}, \ldots \alpha_{n}\right) \subseteq R$, is the set of all linear combinations

$$
\sum_{k=1}^{n} r_{k} \cdot \alpha_{k} \cdot s_{k}
$$

where the $r_{i}$ and $s_{i}$ run over all elements of $R$. The element 0 is an ideal, as well as the whole ring. The set $\alpha_{1}, \ldots, \alpha_{n} \in R$ is called a basis for the ideal $\left(\alpha_{1}, \ldots \alpha_{n}\right)$.
(3) An ideal $\mathfrak{I} \subset R$ is maximal if $\mathfrak{I} \subset \mathfrak{K}$, where $\mathfrak{K}$ is an ideal, implies that $\mathfrak{K}=R$. This is equivalent to saying that for any $r \in R$ with $r \notin \mathfrak{I}$,

$$
\mathfrak{I}+(r)=R
$$

(4) An ideal generated by a single element of $R$ is called a principal ideal.
(5) Given two ideals $\mathfrak{a}$ and $\mathfrak{b}$, their product is the ideal generated by all products $\{(a \cdot b) \mid \forall a \in \mathfrak{a}, b \in \mathfrak{b}\}$.
Remark. We will usually denote ideals by Fraktur letters.
Example. We claim that the ideals of $\mathbb{Z}$ are just the sets

$$
\begin{array}{cc}
(0) & =\{0\} \\
(2)= & \{\ldots,-4,-2,0,2,4,6,8, \ldots\} \\
(3)= & \{\ldots,-6,-3,0,3,6,9,12, \ldots\} \\
& \vdots \\
(n)= & \{n \cdot \mathbb{Z}\}
\end{array}
$$

for various values of $n$. Note that the ideal $(1)=\mathbb{Z}$. An ideal $(n) \subset \mathbb{Z}$ is prime if and only if $n$ is a prime number.

Now, suppose $f_{1}, \ldots, f_{s} \in W=\mathbb{C}\left[X_{1}, \ldots, X_{n}\right]$, and suppose we want to solve the system of algebraic equations

$$
\begin{align*}
f_{1}\left(X_{1}, \ldots, X_{n}\right) & =0 \\
\vdots &  \tag{9.2.2}\\
f_{s}\left(X_{1}, \ldots, X_{n}\right) & =0
\end{align*}
$$

If $g_{1}, \ldots, g_{t} \in W$ is a set of polynomials with the property that

$$
\left(f_{1}, \ldots, f_{s}\right)=\left(g_{1}, \ldots, g_{t}\right)=\mathfrak{B}
$$

- i.e., the $g_{j}$ are another basis for the ideal generated by the $f_{i}$, then the equations in 9.2.2 on the previous page are equivalent to

$$
\begin{aligned}
g_{1}\left(X_{1}, \ldots, X_{n}\right) & =0 \\
\vdots & \\
g_{t}\left(X_{1}, \ldots, X_{n}\right) & =0
\end{aligned}
$$

To see that, note that, since the $f_{i}$ are a basis for $\mathfrak{B}$ and the $g_{i} \in \mathfrak{B}$, we have equations

$$
g_{i}=\sum_{j=1}^{s} a_{i, j} f_{j}
$$

where $a_{i, j} \in W$ for all $i$ and $j$. It follows that $f_{1}=\cdots=f_{s}=0$ implies that $g_{1}=\cdots=g_{t}=0$. Since the $g_{j}$ are also a basis for $\mathfrak{B}$, the reverse implication is also true.

EXAMPLE 9.2.5. Suppose we want to find solutions to the system of algebraic equations

$$
\begin{aligned}
x y & =z^{2} \\
x z & =1 \\
x^{2}+y^{2} & =3
\end{aligned}
$$

We first make these into equations set to zero

$$
\begin{aligned}
x y-z^{2} & =0 \\
x z-1 & =0 \\
x^{2}+y^{2}-3 & =0
\end{aligned}
$$

and find another basis for the ideal these polynomials generate. It turns out ${ }^{1}$ that

$$
\left(x y-z^{2}, x z-1, x^{2}+y^{2}-3\right)=\left(z^{8}-3 z^{2}+1, y-z^{3}, z^{7}-3 z+x\right)
$$

So our original equations are equivalent to the equations

$$
\begin{array}{r}
z^{8}-3 z^{2}+1=0 \\
y-z^{3}=0 \\
z^{7}-3 z+x=0
\end{array}
$$

or

$$
\begin{aligned}
z^{8}-3 z^{2}+1 & =0 \\
y & =z^{3} \\
x & =3 z-z^{7}
\end{aligned}
$$

[^27]so that it follows that our original set of equations had eight solutions: find 8 roots of the polynomial in $z$ and plug them into the equations for $x$ and $y$.

It follows that there are applications to finding "simplified" or "improved" bases for ideals in polynomial rings.

### 9.3. Gröbner bases

One of the most powerful technique for computations in polynomial rings use a special basis for an ideal, called a Gröbner basis. Gröbner bases were discovered by Bruno Buchberger.

Bruno Buchberger 1942 - ) is Professor of Computer Mathematics at Johannes Kepler University in Linz, Austria. In his 1965 Ph.D. thesis (see [9]), he created the theory of Gröbner bases, and has refined this construction in subsequent papers - see $[10,8]$. He named these objects after his advisor Wolfgang Gröbner. Since 1995, he has been active in the Theorema ${ }^{a}$ project at the University of Linz.
In 1987 Buchberger founded and chaired the Research Institute for Symbolic Computation (RISC) at Johannes Kepler University. In 1985 he started the Journal of Symbolic Computation, which has now become the premier publication in the field of computer algebra.
Buchberger also conceived Softwarepark Hagenberg in 1989 and since then has been directing the expansion of this Austrian technology park for software.
${ }^{a}$ A system for automatic theorem-proving.
One key idea in the theory of Gröbner bases involves imposing an ordering on monomials:

Definition 9.3.1. Define an ordering on the elements of $\mathbb{N}^{n}$ and an induced ordering on the monomials of $\mathbb{F}\left[X_{1}, \ldots, X_{n}\right]$ by $\alpha=\left(a_{1}, \ldots, a_{n}\right) \succ$ $\beta=\left(b_{1}, \ldots, b_{n}\right)$ implies that

$$
\Pi x_{i}^{a_{i}} \succ \prod_{i}^{x_{i}}
$$

The ordering of $\mathbb{N}^{n}$ must satisfy the conditions:
(1) if $\alpha \succ \beta$ and $\gamma \in \mathbb{N}^{n}$, then $\alpha+\gamma \succ \beta+\gamma$
(2) $\succ$ is a well-ordering: every set of elements of $\mathbb{N}^{n}$ has a minimal element.
For any polynomial $f \in \mathbb{F}\left[X_{1}, \ldots, X_{n}\right]$, let $\operatorname{LT}(f)$ denote its leading term in this ordering - the polynomial's highest-ordered monomial with its coefficient.

REMARK. Condition 1 implies that the corresponding ordering of monomials is preserved by multiplication by a monomial. Condition 2 implies that there are no infinite descending sequences of monomials.

Definition 9.3.2. Suppose an ordering has been chosen for the monomials of $\mathbb{F}\left[X_{1}, \ldots, X_{n}\right]$. If $\mathfrak{a} \in \mathbb{F}\left[X_{1}, \ldots, X_{n}\right]$ is an ideal, let $\operatorname{LT}(\mathfrak{a})$ denote the ideal generated by the leading terms of the polynomials in $\mathfrak{a}$.
(1) If $\mathfrak{a}=\left(f_{1}, \ldots, f_{t}\right)$, then $\left\{f_{1}, \ldots, f_{t}\right\}$ is a Gröbner basis for $\mathfrak{a}$ if

$$
\operatorname{LT}(\mathfrak{a})=\left(\operatorname{LT}\left(f_{1}\right), \ldots, \operatorname{LT}\left(f_{t}\right)\right)
$$

(2) A Gröbner basis $\left\{f_{1}, \ldots, f_{t}\right\}$ is minimal if the leading coefficient of each $f_{i}$ is 1 and for each $i$

$$
\operatorname{LT}\left(f_{i}\right) \notin\left(\operatorname{LT}\left(f_{1}\right), \ldots, \operatorname{LT}\left(f_{i-1}\right), \operatorname{LT}\left(f_{i+1}\right), \ldots \operatorname{LT}\left(f_{t}\right)\right)
$$

(3) A Gröbner basis $\left\{f_{1}, \ldots, f_{t}\right\}$ is reduced if the leading coefficient of each $f_{i}$ is 1 and for each $i$ and no monomial of $f_{i}$ is contained in

$$
\left(\operatorname{LT}\left(f_{1}\right), \ldots, \operatorname{LT}\left(f_{i-1}\right), \operatorname{LT}\left(f_{i+1}\right), \ldots \operatorname{LT}\left(f_{t}\right)\right)
$$

REMARK. There are many different types of orderings that can be used and a Gröbner basis with respect to one ordering will generally not be one with respect to another.

Definition 9.3.3. The two most common orderings used are:
(1) Lexicographic ordering ${ }^{2}$. Let $\mathbb{N}$ denote the natural numbers and let $\mathbb{N}^{n}$ represents sequences of $n$ natural numbers. Let $\alpha=\left(a_{1}, \ldots, a_{n}\right), \beta=\left(b_{1}, \ldots, b_{n}\right) \in \mathbb{N}^{n}$. Then $\alpha>\beta \in \mathbb{N}^{n}$ if, in the vector difference $\alpha-\beta \in \mathbb{Z}^{n}$, the leftmost nonzero entry is positive - and we define

$$
\prod X_{i}^{a_{i}} \succ \prod X_{i}^{b_{i}}
$$

so

$$
X Y^{2} \succ Y^{3} Z^{4}
$$

This is the ordering that we will use.
(2) Graded reverse lexicographic order. Here, monomials are first ordered by total degree - i.e., the sum of the exponents. Ties are resolved lexicographically (in reverse - higher lexicographic order represents a lower monomial).

Remark. In Graded Reverse Lexicographic order, we get

$$
X^{4} Y^{4} Z^{7} \succ X^{5} Y^{5} Z^{4}
$$

since the total degree is greater. As remarked above, Gröbner bases depend on the ordering, $\succ$ : different orderings give different bases and even different numbers of basis elements.

Gröbner bases give an algorithmic procedure for deciding whether a polynomial is contained in an ideal and whether two ideals are equal.

### 9.4. Buchberger's Algorithm

Unfortunately, Buchberger's algorithm can have exponential time-complexity - for graded-reverse lexicographic ordering - and doubly-exponential ( $e^{e^{n}}$ ) complexity for lexicographic ordering (see [31]). This, incidentally, is why we discussed resultants of polynomials: the complexity of computing Gröbner bases (especially with lexicographic ordering, which leads to the Elimination Property) can easily overwhelm

[^28]powerful computers. Computing resultants is relatively simple (they boil down to computing determinants).

In practice it seems to have a reasonable running time. In special cases, we have:
(1) For a system of linear polynomials, Buchberger's algorithm reduces to Gaussian Elimination for putting a matrix in upper triangular form.
(2) For polynomials over a single variable, it becomes Euclid's algorithm for finding the greatest common divisor for two polynomials.
In 1950, Gröbner published a paper ([19]) that explored an algorithm for computing Gröbner bases, but could not prove that it ever terminated. One of Buchberger's signal contributions were the introduction of constructs called S-polynomials. For details, see [40, chapter 5].

The main property of Gröbner bases that will interest us is:
Proposition 9.4.1 (Elimination Property). Suppose $\left\{g_{1}, \ldots, g_{j}\right\}$ is a Gröbner basis for the ideal $\mathfrak{a} \in \mathbb{C}\left[X_{1}, \ldots, X_{n}\right]$, computed using lexicographic ordering with

$$
X_{1} \succ X_{2} \succ \cdots \succ X_{n}
$$

If $1 \leq t \leq n$, then

$$
\mathfrak{a} \cap \mathbb{C}\left[X_{t}, \ldots, X_{n}\right]
$$

has a Gröbner basis that is

$$
\left\{g_{1}, \ldots, g_{j}\right\} \cap \mathbb{C}\left[X_{t}, \ldots, X_{n}\right]
$$

REMARK. This is particularly important in using Gröbner bases to solve systems of algebraic equations. Here, we want to eliminate variables if possible and isolate other variables. In example 9.2.5 on page 156, we have the ideal

$$
\mathfrak{B}=\left(x y-z^{2}, x z-1, x^{2}+y^{2}-3\right)
$$

and can find a Gröbner basis for it with lexicographic ordering with $x \succ$ $y \succ z$ of

$$
\left(z^{8}-3 z^{2}+1, y-z^{3}, z^{7}-3 z+x\right)
$$

Here, the basis element $z^{8}-3 z^{2}+1$ is an element of $\mathfrak{B} \cap \mathbb{C}[z] \subset \mathbb{C}[x, y, z]$ and the variables $x$ and $y$ have been eliminated from it. It follows that $z$, alone, must satisfy

$$
z^{8}-3 z^{2}+1=0
$$

and we can solve for $x$ and $y$ in terms of $z$ :

$$
\begin{aligned}
& y=z^{3} \\
& x=3 z-z^{7}
\end{aligned}
$$

Proof. See [40, chapter 5].
Maxima has a package that computes Gröbner bases using lexicographic ordering. To load it, type

Its main commands ${ }^{3}$ are
poly_grobner(poly-list, var-list)
and
poly_reduced_grobner (poly-list, var-list)
For example:
poly_grobner ([ $\left.\left.x^{\wedge} 2+y^{\wedge} 2, x^{\wedge} 3-y \wedge 4\right],[x, y]\right)$
returns

$$
\left(x^{2}+y^{2}, x^{3}-y^{4}, x^{4}+x y^{2}, y^{6}+y^{4}\right)
$$

— the Gröbner basis with lexicographic order: $x \succ y$. The command
poly_reduced_grobner $\left(\left[x^{\wedge} 2+y^{\wedge} 2, x^{\wedge} 3-y^{\wedge} 4\right],[x, y]\right)$
returns

$$
\left[y^{2}+x^{2}, y^{4}+x y^{2}, y^{6}+y^{4}\right]
$$

a Gröbner basis with extraneous elements deleted.

### 9.5. Consistency of algebraic equations

In linear algebra it's well known that systems like

$$
\begin{array}{r}
x+y=2 \\
2 x+2 y=3
\end{array}
$$

have no solution; they are inconsistent.
Given a system of algebraic equations

$$
\begin{gather*}
f_{1}\left(x_{1}, \ldots, x_{n}\right)=v_{1}  \tag{9.5.1}\\
\vdots \\
f_{m}\left(x_{1}, \ldots, x_{n}\right)=v_{m}
\end{gather*}
$$

we construct an ideal

$$
\mathfrak{A}=\left(f_{1}\left(x_{1}, \ldots, x_{n}\right)-v_{1}, \ldots, f_{m}\left(x_{1}, \ldots, x_{n}\right)-v_{m}\right)
$$

and try to find an "improved" basis for it, i.e,

$$
\mathfrak{A}=\left(b_{1}, \ldots, b_{k}\right)
$$

so that the original equations are equivalent to

$$
b_{1}=\cdots=b_{k}=0
$$

Suppose we discover that

$$
1 \in \mathfrak{A}
$$

This implies that

$$
\mathfrak{A}=(1)
$$

and that

$$
1=0
$$

[^29]is equivalent to the original set of equations. Since this is clearly impossible, it follows that the original set of equations was inconsistent.

A theorem due to David Hilbert, called the Nullstellensatz (see [40], chapter $12,12.2 .3$ ) shows that inconsistent equations always imply that $1 \in$ $\mathfrak{A}$.

David Hilbert (1862-1943) was one of the most influential mathematicians in the $19^{\text {th }}$ and early $20^{\text {th }}$ centuries, having contributed to algebraic and differential geometry, physics, and many other fields.

We conclude that
The system of equations in 9.5 .1 on the preceding page is inconsistent if and only if $1 \in \mathfrak{A}$, which happens if and only if

$$
\begin{gathered}
\text { poly_reduced_grobner ([f1-v1, } \underset{[\mathrm{x} 1, \ldots, \mathrm{fn}])}{ } \mathrm{fm-vm]}, \\
\hline
\end{gathered}
$$

returns [1].

## Exercises.

1. Solve the equations

$$
\begin{aligned}
& x^{2}+y^{2}=0 \\
& x^{3}-y^{4}=0
\end{aligned}
$$

2. Solve the equations

$$
\begin{aligned}
a_{1} a_{2}-b_{1} b_{2}+a_{1}-1 & =0 \\
a_{2} b_{1}+a_{1} b_{2}+b_{1}-1 / 2 & =0 \\
a_{1}^{2}+b_{1}^{2}-1 & =0 \\
a_{2}^{2}+b_{2}^{2}-1 & =0
\end{aligned}
$$

3. If

$$
\left(a^{2}+1\right)\left(b^{2}+1\right)+25=10(a+b)
$$

and

$$
a b=1
$$

what is

$$
a^{3}+b^{3}
$$

equal to?
4. Solve

$$
\begin{aligned}
& x^{2}+x y+y^{2}=39 \\
& y^{2}+y z+z^{2}=49 \\
& z^{2}+z x+x^{2}=19
\end{aligned}
$$

5. Find a solution to the system

$$
\begin{aligned}
a 1 \cdot x 1^{5}+a 2 \cdot x 2^{5}+a 3 \cdot x 3^{5} & =1 / 6 \\
a 1 \cdot x 1^{4}+a 2 \cdot x 2^{4}+a 3 \cdot x 3^{4} & =1 / 5 \\
a 1 \cdot x 1^{3}+a 2 \cdot x 2^{3}+a 3 \cdot x 3^{3} & =1 / 4 \\
a 1 \cdot x 1^{2}+a 2 \cdot x 2^{2}+a 3 \cdot x 3^{2} & =1 / 3 \\
a 1 \cdot x 1+a 2 \cdot x 2+a 3 \cdot x 3 & =1 / 2 \\
a 1+a 2+a 3 & =1
\end{aligned}
$$

## CHAPTER 10

## Robot motion-planning

"Geometry is one and eternal shining in the mind of God. That share in it accorded to men is one of the reasons that Man is the image of God."

- Johannes Kepler, Conversation with the Sidereal Messenger (an open letter to Galileo Galilei), [36].

### 10.1. A simple robot-arm

Suppose we have a robot-arm with two links, as in figure 10.1.1.

If we assume that both links are of length $\ell$, suppose the second link were attached to the origin rather than at the end of the second link.

Then its endpoint would be at (see equation 7.5 .2 on page 132)

$$
\begin{aligned}
{\left[\begin{array}{c}
\ell \cos (\phi) \\
\ell \sin (\phi) \\
1
\end{array}\right] } & =\left[\begin{array}{ccc}
\cos (\phi) & -\sin (\phi) & 0 \\
\sin (\phi) & \cos (\phi) & 0 \\
0 & 0 & 1
\end{array}\right]\left[\begin{array}{lll}
1 & 0 & \ell \\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right]\left[\begin{array}{l}
0 \\
0 \\
1
\end{array}\right] \\
& =\left[\begin{array}{ccc}
\cos (\phi) & -\sin (\phi) & \ell \cos (\phi) \\
\sin (\phi) & \cos (\phi) & \ell \sin (\phi) \\
0 & 0 & 1
\end{array}\right]\left[\begin{array}{l}
0 \\
0 \\
1
\end{array}\right]
\end{aligned}
$$

In other words, the effect of moving from the origin to the end of the second link (attached to the origin) is
(1) displacement by $\ell$ - so that $(0,0)$ is moved to $(\ell, 0)=(\ell, 0,1) \in \mathbb{R}^{3}$.
(2) rotation by $\phi$

This is the effect of the second link on all of $\mathbb{R}^{2}$. If we want to compute the effect of both links, insert the first link into the system - i.e. rigidly attach the second link to the first, displace by $\ell$, and rotate by $\theta$. The effect is

Figure 10.1.1. A simple robot arm
equivalent to multiplying by

$$
M_{2}=\left[\begin{array}{ccc}
\cos (\theta) & -\sin (\theta) & \ell \cos (\theta) \\
\sin (\theta) & \cos (\theta) & \ell \sin (\theta) \\
0 & 0 & 1
\end{array}\right]
$$

It is clear that we can compute the endpoint of any number of links in this manner - always inserting new links at the origin and moving the rest of the chain accordingly.

At this point, the reader might wonder
Where does algebra enter into all of this?
The point is that we do not have to deal with trigonometric functions until the very last step. If $a, b \in \mathbb{R}$ are numbers with the property that

$$
\begin{equation*}
a^{2}+b^{2}=1 \tag{10.1.1}
\end{equation*}
$$

there is a unique angle $\theta$ with $a=\cos (\theta)$ and $b=\sin (\theta)$. This enables us to replace the trigonometric functions by real numbers that satisfy equation 10.1.1 and derive purely algebraic equations for
(1) the set of points in $\mathbb{R}^{2}$ reachable by a robot-arm
(2) strategies for reaching those points (solving for explicit angles).

In the simple example above, let $a_{1}=\cos (\theta), b_{1}=\sin (\theta), a_{2}=\cos (\phi), b_{2}=$ $\sin (\phi)$ so that our equations for the endpoint of the second link become

$$
\begin{aligned}
{\left[\begin{array}{l}
x \\
y \\
1
\end{array}\right] } & =\left[\begin{array}{ccc}
a_{1} & -b_{1} & \ell a_{1} \\
b_{1} & a_{1} & \ell b_{1} \\
0 & 0 & 1
\end{array}\right]\left[\begin{array}{c}
\ell a_{2} \\
\ell b_{2} \\
1
\end{array}\right] \\
& =\left[\begin{array}{c}
\ell a_{1} a_{2}-\ell b_{2} b_{1}+\ell a_{1} \\
\ell b_{1} a_{2}+\ell a_{1} b_{2}+\ell b_{1} \\
1
\end{array}\right]
\end{aligned}
$$

It follows that the points $(x, y)$ reachable by this link are those for which the system of equations

$$
\begin{align*}
\ell a_{1} a_{2}-\ell b_{2} b_{1}+\ell a_{1}-x & =0 \\
\ell b_{1} a_{2}+\ell a_{1} b_{2}+\ell b_{1}-y & =0 \\
a_{1}^{2}+b_{1}^{2}-1 & =0 \\
a_{2}^{2}+b_{2}^{2}-1 & =0 \tag{10.1.2}
\end{align*}
$$

has real solutions (for $a_{i}$ and $b_{i}$ ). Given values for $x$ and $y$, we can solve for the set of configurations of the robot arm that will reach $(x, y)$. We set the lengths of the robot arms to 1 . The system of equations 10.1.2 gives rise to the ideal
$r=\left(a_{1} a_{2}-b_{1} b_{2}+a_{1}-x, a_{2} b_{1}+a_{1} b_{2}+b_{1}-y, a_{1}^{2}+b_{1}^{2}-1, a_{2}^{2}+b_{2}^{2}-1\right)$
in $\mathbb{C}\left[a_{1}, a_{2}, b_{1}, b_{2}\right]$. If we set $x=1$ and $y=1 / 2$, the Gröbner basis of $r$ (using the command ' $\operatorname{Basis}\left(\mathrm{r}, \mathrm{plex}\left(a_{1}, b_{1}, a_{2}, b_{2}\right)\right.$ )' in Maple) is

$$
\left(-55+64 b_{2}{ }^{2}, 8 a_{2}+3,16 b_{2}-5+20 b_{1},-5-4 b_{2}+10 a_{1}\right)
$$

Figure 10.1.2. Reaching a point
from which we deduce that $a_{2}=-3 / 8$ and $b_{2}$ can be either $+\sqrt{55} / 8$ in which case

$$
\begin{aligned}
a_{1} & =1 / 2+\sqrt{55} / 20 \\
b_{1} & =1 / 4-\sqrt{55} / 10
\end{aligned}
$$

or $-\sqrt{55} / 8$ in which case

$$
\begin{aligned}
& a_{1}=1 / 2-\sqrt{55} / 20 \\
& b_{1}=1 / 4+\sqrt{55} / 10
\end{aligned}
$$

Another question we might ask is:
For what values of $x$ are points on the line $y=1-2 x$ reachable?
In this case, we start with the ideal

$$
\begin{aligned}
r=\left(a_{1} a_{2}-b_{1} b_{2}+a_{1}-x, a_{2} b_{1}+a_{1} b_{2}+b_{1}\right. & +2 x-1 \\
& \left.a_{1}^{2}+b_{1}^{2}-1, a_{2}^{2}+b_{2}^{2}-1\right)
\end{aligned}
$$

and get the Gröbner basis

```
poly_reduced_grobner ([a1*a2-b1*b2+a1-x,
a2*b1+a1*b2+b1+2*x-1,a1^2+b1^2-1,a2^2+b2^2-1],
[a1,b1,a2,b2,x])
```

to get

$$
\begin{aligned}
{\left[-5 x^{2}+4 x+\right.} & 2 a_{2}+1 \\
& -25 x^{4}+40 x^{3}-6 x^{2}-8 x-4 b_{2}^{2}+3 \\
& -5 x^{3}+4 x^{2}+4 b_{2} x+3 x+4 b_{1} b_{2}-2 b_{2} \\
& -5 x^{2}-5 b_{1} x+4 x-b_{2}+2 b_{1}+a_{1}-1 \\
- & \left.10 x^{3}-10 b_{1} x^{2}+13 x^{2}-2 b_{2} x+8 b_{1} x-6 x-2 b_{1}+1\right]
\end{aligned}
$$

FIGURE 10.2.1. A more complicated robot arm

The second line

$$
-25 x^{4}+40 x^{3}-6 x^{2}-8 x-4 b_{2}^{2}+3
$$

is significant: Since all variables are real, $4 b_{2}^{2} \geq 0$, which requires

$$
\begin{equation*}
-25 x^{4}+40 x^{3}-6 x^{2}-8 x+3 \geq 0 \tag{10.1.3}
\end{equation*}
$$

If we type
solve $\left(-25 * x^{\wedge} 4+40 * x^{\wedge} 3-6 * x^{\wedge} 2-8 * x+3=0,[x]\right)$
we get

$$
\left[x=-\frac{\sqrt{19}-2}{5}, x=\frac{\sqrt{19}+2}{5}, x=-\frac{i-2}{5}, x=\frac{i+2}{5}\right]
$$

Since our variables are all real, we discard the last two solutions. Since the polynomial is $>0$ for $x=0$, we conclude that solution to the inequality in 10.1.3 is

$$
x \in\left[\frac{2-\sqrt{19}}{5}, \frac{2+\sqrt{19}}{5}\right]
$$

- so those are the only points on the line $y=1-2 x$ that the robot-arm can reach.

### 10.2. A more complex robot-arm

We conclude this chapter with a more complicated robot-arm in figure 10.2.1- somewhat like a Unimation Puma $560^{1}$.

It has:
(1) A base of height $\ell_{1}$ and motor that rotates the whole assembly by $\phi_{1}$ - with 0 being the positive $x$-axis.
(2) An arm of length $\ell_{2}$ that can be moved forward or backward by an angle of $\theta_{1}$ - with 0 being straight forward (in the positive $x$-direction).

[^30](3) A second arm of length $\ell_{3}$ linked to the first by a link of angle $\theta_{2}$, with 0 being when the second arm is in the same direction as the first.
(4) A little "hand" of length $\ell_{4}$ that can be inclined from the second arm by an angle of $\theta_{3}$ and rotated perpendicular to that direction by an angle $\phi_{2}$.
We do our computations in $\mathbb{R}^{4}$, start with the hand and work our way to the base. The default position of the hand is on the origin and pointing in the positive $x$-direction. It displaces the origin in the $x$-direction by $\ell_{2}$, represented by the matrix
\[

D_{0}=\left[$$
\begin{array}{cccc}
1 & 0 & 0 & \ell_{2} \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{array}
$$\right]
\]

The angle $\phi_{1}$ rotates the arm in the $x y$-plane, and is therefore represented by

$$
\left[\begin{array}{cccc}
\cos \left(\phi_{1}\right) & -\sin \left(\phi_{1}\right) & 0 & 0 \\
\sin \left(\phi_{1}\right) & \cos \left(\phi_{1}\right) & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{array}\right]
$$

or

$$
Z_{1}=\left[\begin{array}{cccc}
a_{1} & -b_{1} & 0 & 0 \\
b_{1} & a_{1} & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{array}\right]
$$

with $a_{1}=\cos \left(\phi_{2}\right)$ and $b_{1}=\sin \left(\phi_{2}\right)$. The "wrist" inclines the hand in the $x z$-plane by an angle of $\theta_{3}$, given by the matrix

$$
Z_{2}=\left[\begin{array}{cccc}
a_{2} & 0 & -b_{2} & 0 \\
0 & 1 & 0 & 0 \\
b_{2} & 0 & a_{2} & 0 \\
0 & 0 & 0 & 1
\end{array}\right]
$$

with $a_{2}=\cos \left(\theta_{3}\right)$ and $b_{2}=\sin \left(\theta_{3}\right)$ and the composite is

$$
Z_{2} Z_{1} D_{0}=\left[\begin{array}{cccc}
a_{2} & -b_{2} b_{1} & -b_{2} a_{1} & a_{2} \ell_{4} \\
0 & a_{1} & -b_{1} & 0 \\
b_{2} & a_{2} b_{1} & a_{2} a_{1} & b_{2} \ell_{4} \\
0 & 0 & 0 & 1
\end{array}\right]
$$

The second arm displaces everything by $\ell_{3}$ in the $x$-direction, giving

$$
D_{1}=\left[\begin{array}{cccc}
1 & 0 & 0 & \ell_{3} \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{array}\right]
$$

so

$$
D_{1} Z_{2} Z_{1} D_{0}=\left[\begin{array}{cccc}
a_{2} & -b_{2} b_{1} & -b_{2} a_{1} & a_{2} \ell_{4}+\ell_{3} \\
0 & a_{1} & -b_{1} & 0 \\
b_{2} & a_{2} b_{1} & a_{2} a_{1} & b_{2} \ell_{4} \\
0 & 0 & 0 & 1
\end{array}\right]
$$

so and then inclines it by $\theta_{2}$ in the $x z$-plane, represented by

$$
Z_{3}=\left[\begin{array}{cccc}
a_{3} & 0 & -b_{3} & 0 \\
0 & 1 & 0 & 0 \\
b_{3} & 0 & a_{3} & 0 \\
0 & 0 & 0 & 1
\end{array}\right]
$$

so that $Z_{3} D_{1} Z_{2} Z_{1} D_{0}$ is

$$
\left[\begin{array}{cccc}
a_{3} a_{2}-b_{3} b_{2} & \left(-a_{3} b_{2}-b_{3} a_{2}\right) b_{1} & \left(-a_{3} b_{2}-b_{3} a_{2}\right) a_{1} & \left(a_{3} a_{2}-b_{3} b_{2}\right) \ell_{4}+a_{3} \ell_{3} \\
0 & a_{1} & -b_{1} & 0 \\
b_{3} a_{2}+a_{3} b_{2} & \left(a_{3} a_{2}-b_{3} b_{2}\right) b_{1} & \left(a_{3} a_{2}-b_{3} b_{2}\right) a_{1} & \left(b_{3} a_{2}+a_{3} b_{2}\right) \ell_{4}+b_{3} \ell_{3} \\
0 & 0 & 0 & 1
\end{array}\right]
$$

Continuing in this fashion, we get a huge matrix, $Z$. To find the endpoint of the robot-arm, multiply

$$
\left[\begin{array}{l}
0 \\
0 \\
0 \\
1
\end{array}\right]
$$

(representing the origin of $\mathbb{R}^{3} \subset \mathbb{R}^{4}$ ) by $Z$ to get
(10.2.1) $\left[\begin{array}{l}x \\ y \\ z \\ 1\end{array}\right]=$
$\left[\begin{array}{c}\left(\left(a_{5} a_{3}+b_{5} b_{4} b_{3}\right) a_{2}+\left(-a_{5} b_{3}+b_{5} b_{4} a_{3}\right) b_{2}\right) \ell_{4}+\left(a_{5} a_{3}+b_{5} b_{4} b_{3}\right) \ell_{3}+a_{5} \ell_{2} \\ \left(\left(b_{5} a_{3}-a_{5} b_{4} b_{3}\right) a_{2}+\left(-b_{5} b_{3}-a_{5} b_{4} a_{3}\right) b_{2}\right) \ell_{4}+\left(b_{5} a_{3}-a_{5} b_{4} b_{3}\right) \ell_{3}+b_{5} \ell_{2} \\ \left(a_{4} b_{3} a_{2}+a_{4} a_{3} b_{2}\right) \ell_{4}+a_{4} b_{3} \ell_{3}+\ell_{1} \\ 1\end{array}\right]$
where $a_{3}=\cos \left(\theta_{2}\right), b_{3}=\sin \left(\theta_{2}\right), a_{4}=\cos \left(\theta_{1}\right), b_{4}=\sin \left(\theta_{1}\right)$ and $a_{5}=$ $\cos \left(\phi_{1}\right), b_{5}=\sin \left(\phi_{1}\right)$. Note that $a_{i}^{2}+b_{i}^{2}=1$ for $i=1, \ldots, 5$. We are also interested in the angle that the hand makes (for instance, if we want to pick
something up). To find this, compute

$$
\begin{align*}
Z\left[\begin{array}{l}
1 \\
0 \\
0 \\
1
\end{array}\right]-Z\left[\begin{array}{l}
0 \\
0 \\
0 \\
1
\end{array}\right]= & Z\left[\begin{array}{l}
1 \\
0 \\
0 \\
0
\end{array}\right]=  \tag{10.2.2}\\
& {\left[\begin{array}{c}
\left(a_{5} a_{3}+b_{5} b_{4} b_{3}\right) a_{2}+\left(-a_{5} b_{3}+b_{5} b_{4} a_{3}\right) b_{2} \\
\left(b_{5} a_{3}-a_{5} b_{4} b_{3}\right) a_{2}+\left(-b_{5} b_{3}-a_{5} b_{4} a_{3}\right) b_{2} \\
a_{4} b_{3} a_{2}+a_{4} a_{3} b_{2} \\
0
\end{array}\right] }
\end{align*}
$$

The numbers in the top three rows of this matrix are the direction-cosines of the hand's direction. We can ask what points the arm can reach with its hand aimed in a particular direction.If we set $\ell_{1}=\ell_{2}=1$, equation 10.2.1 on the facing page implies that the endpoint of the robot-arm are solutions to the system

$$
\begin{align*}
a_{5} a_{4} a_{3}-a_{5} b_{4} b_{3}+a_{5} a_{4}-x & =0 \\
b_{5} a_{4} a_{3}-b_{5} b_{4} b_{3}+b_{5} a_{4}-y & =0 \\
b_{4} a_{3}+a_{4} b_{3}+b_{4}-z & =0 \\
a_{3}^{2}+b_{3}^{2}-1 & =0 \\
a_{4}^{2}+b_{4}^{2}-1 & =0 \\
a_{5}^{2}+b_{5}^{2}-1 & =0 \tag{10.2.3}
\end{align*}
$$

If we want to know which points it can reach with the hand pointing in the direction

$$
\left[\begin{array}{l}
1 / \sqrt{3} \\
1 / \sqrt{3} \\
1 / \sqrt{3}
\end{array}\right]
$$

use equation 10.2.2 to get

$$
\begin{align*}
\left(a_{5} a_{4} a_{3}-a_{5} b_{4} b_{3}\right) a_{2}+\left(-a_{5} a_{4} b_{3}-a_{5} b_{4} a_{3}\right) b_{2}-1 / \sqrt{3} & =0 \\
\left(b_{5} a_{4} a_{3}-b_{5} b_{4} b_{3}\right) a_{2}+\left(-b_{5} a_{4} b_{3}-b_{5} b_{4} a_{3}\right) b_{2}-1 / \sqrt{3} & =0 \\
\left(b_{4} a_{3}+a_{4} b_{3}\right) a_{2}+\left(a_{4} a_{3}-b_{4} b_{3}\right) b_{2}-1 / \sqrt{3} & =0 \\
a_{2}^{2}+b_{2}^{2}-1 & =0 \tag{10.2.4}
\end{align*}
$$

We regard these terms (in equations 10.2.3 and 10.2.4 as generators of an ideal, $\mathfrak{P}$.

To understand possible configurations of the robot-arm, we compute a Gröbner basis of $\mathfrak{P}$ with lexicographic ordering. Unfortunately, we run up against the $e^{e^{n}}$-execution time: This Maxima program

```
poly_grobner([ a5*a4*a3-a5*b4*b3+a5*a4-x,
b5*a4*a3-b5*b4*b3+b5*a4-y,
b4*a3+a4*b3+b4-z,
(a5*a4*a3-a5*b4*b3)*a2+(-a5*a4*b3-a5*b4*a3)*b2-1/sqrt (3),
(b5*a4*a3-b5*b4*b3)*a2+(-b5*a4*b3-b5*b4*a3)*b2-1/sqqrt (3),
(b4*a3+a4*b3)*a2+(a4*a3-b4*b3)*b2-1/sqrt (3),
```

```
a2^2+b2^2-1,
a3^2+b3^2-1,
a4^2+b4^2-1,
a5^2+b5^2 -1],
[a5,a4,a3,a2,b5,b4,b3,b2,x,y,z ]);
```

runs for several hours and crashes due to memory issues. We can try another piece of free software, Macaulay 2, which can compute Gröbner bases (among other things). The program

```
R=QQ[a_5 ,a_4,a_3,a_2 ,b_5 ,b_4,b_3,b_2 ,w,x y , z,
    MonomialOrder=>Lex]
Z=ideal(a_5 *a_4*a_3-a_5 *b_4*b_3+a_5 *a_4-x,
b_5*a_4*a_3-b_5*b_4*b_3+b_5*a_4-y,
b_4*a_3+a_4*b_3+b_4-z,
(a_5*a_4*a_3-a_5*b_4*b_3)*a_2+
(-a_5*a_4*b_3-a_5*b_4*a_3)*b_2-w,
(b_5*a_4*a_3-b_5*b_4*b_3)*a_2+
(-b_5*a_4*b_3-b_5 5 b_4*a_3)*b_2-w,
(b_4*a_3+a_4*b_3)*a_2 +(a_4*a_3-b_4*b_3)*b_2-w,
a_2^2+b_2^2-1,
a_3^2+b_3^2-1,
a_4^2+b_4^2-1,
a_5^2+b_5^2-1
)
P=gb Z
gens P
```

runs for several hours and crashes when it tries to allocate more than 4 gigabytes of memory (my computer has more, but the system seems reluctant to allocate it).

We finally use the free system, Singular, from the University of Karlsruhe in Germany. It uses newer and greatly improved algorithms for computing Gröbner bases. It is, perhaps, the most advanced such program in the world.

The cryptic Singular program

```
option(redSB); // Causes Singular to compute a reduced
    // Groebner basis
ring R=(0),(a_5,a_4,a_3,a_2,b_5,b_4,b_3,b_2,x,y,z,w),lp;
// numeric 0=rational coefficients
// lp=lexicographic ordering
ideal s = a_5*a_4*a_3-a_5*b_4*b_3+a_5*a_4-x,
b_5*a_4*a_3-b_5*b_4*b_3+b_5*a_4-y,
b_4*a_3+a_4*b_3+b_4-z,
(a_5*a_4*a_3-a_5*b_4*b_3)*a_2+
    (-a_5*a_4*b_3-a_5 b b_4*a_3)*b_2-w,
(b_5*a_4*a_3-b_5*b_4*b_3)*a_2+
    (-b_5*a_4*b_3-b_5*b_4*a_3)*b_2-w,
(b_4*a_3+a_4*b_3)*a_2+(a_4*a_3-b_4*b_3)*b_2-w,
```

```
a_2^2+b_2^2-1,
a_3^2+b_3^2-1,
a_4^2+b_4^2-1,
a_5^2+b_5^2-1;
slimgb(s); // Causes Singular to try to use the
    // smallest expressions
```

immediately comes back with the results in appendix A on page 225. Here ' 0 ' is the digit zero, which represents rational coefficients for the polynomials. Since $1 / \sqrt{3}$ is not rational, we make it into a variable.

Incidentally, the commercial computer algebra software, Maple 16, also comes back with an answer quickly, but an incorrect one. This author has not had the opportunity to test the other major commercial system: Mathematica.

Several things leap out at us from the long list in appendix A on page 225 :
(1) $3^{*} \mathrm{w}^{\wedge} 2-1$
(2) $2^{*} \mathrm{~b} \_5^{\wedge} 2-1$
(3) $a \_5-b \_5$
(4) $x-y$

Since all elements of the Gröbner basis are implicitly set to 0 , this means $w= \pm 1 / \sqrt{3}$; no other values are possible ${ }^{2}$. The second line implies that $x=y$ - a very severe restriction on where the robot-arm can reach (when the hand is pointed in that direction).

This example was meant to illustrate what is called "the combinatorial explosion" where even fast computers can be overwhelmed by the complexities of a problem.

Maxima will be able to handle all of the other examples we do (and the exercises!).

Suppose we want to reach the point $(1,1,1)$ and we don't care how the hand is aligned. We try the Maxima commands

```
poly_reduced_grobner ([ a5*a4*a3-a5*b4*b3+a5*a4-1,
b5*a4*a3-b5*b4*b3+b5*a4-1,
b4*a3+a4*b3+b4-1,
a2^2+b2^2-1,
a3^2+b3^2-1,
a4^2+b4^2-1,
a5^2+b5^^2-1],
[a5,a4,a3,a2 ,b5,b4,b3,b2 ]);
```

and Maxima comes back (immediately!) with

$$
\begin{array}{r}
{\left[b 2^{2}+a 2^{2}-1,12 b 4^{2}-12 b 4+1,4 b 3^{2}-3,\right.} \\
2 b 3 b 4-b 3+a 5,-6 b 3 b 4+4 b 3-3 a 4,1-2 a 3, b 5+2 b 3 b 4-b 3]
\end{array}
$$

[^31]Conclusions:
$\triangleright a 3=1 / 2$
$\triangleright b 3= \pm \sqrt{3 / 4}$
$\triangleright$ solve $(12 * \mathrm{~b} 4 \wedge 2-12 * \mathrm{~b} 4+1=0, \mathrm{~b} 4)$ gives $\left[\mathrm{b} 4=-\frac{\sqrt{6}-3}{6}, \mathrm{~b} 4=\frac{\sqrt{6}+3}{6}\right]$
$\triangleright$ b5, a4, and a5 are uniquely determined by b3 and b4: $a 5=b 3-$ $2 b 3 b 4, b 5=b 3-2 b 3 b 4=a 5, a 4=4 b 3 / 3-2 b 3 b 4$
$\triangleright \mathrm{a} 2$ and b 2 are free, subject only to the equation $a 2^{2}+b 2^{2}=1$. They rotate the hand and have no effect on its position.
So there an infinite number of solutions and, for each choice of a2 and b2, there are 4 solutions for the other variables:
(1) $a 3=1 / 2, b 3=\sqrt{3 / 4}, b 4=-\frac{\sqrt{6}-3}{6}=.09175117$, $a 4=\frac{\sqrt{3} \sqrt{6}+\sqrt{3}}{6}=.995781, a 5=1 / \sqrt{2}=b 5$
(2) $a 3=1 / 2, b 3=-\sqrt{3 / 4}, \mathrm{~b} 4=-\frac{\sqrt{6}-3}{6}=.09175117$, $a 4=-\frac{\sqrt{3} \sqrt{6}+\sqrt{3}}{6}=-.995781, a 5=-1 / \sqrt{2}=b 5$
(3) $a 3=1 / 2, b 3=\sqrt{3 / 4}, b 4=\frac{\sqrt{6}+3}{6}=.9082482, a 4=\frac{\sqrt{3} \cdot \sqrt{6}-\sqrt{3}}{6}=$ .4184316, $a 5=1 / \sqrt{2}=b 5$
(4) $a 3=1 / 2, b 3=-\sqrt{3 / 4}, b 4=\frac{\sqrt{6}+3}{6}=.9082482$, $a 4=-\frac{\sqrt{3} \cdot \sqrt{6}-\sqrt{3}}{6}=-.4184316, a 5=-1 / \sqrt{2}=b 5$

## EXERCISES.

1. How far can the robot-arm in figure on page 166 reach? Hint: add $x^{2}+y^{2}+z^{2}-r^{2}$ to the list of expressions representing the robot-arm and find reasonable values of $r$.
2. How can the robot-arm in figure on page 166 reach the point $(1 / 2,-1 / 3,1)$ ?
3. For the robot-arm in figure on page 166, why are there always an even number of solutions (ignoring a2 and b2)? (Hint: consider its geometry).

## Differential Game Theory, a Drive-by

"Everything has been thought of before, but the problem is to think of it again."
— Johann Wolfgang von Goethe.

### 11.1. Dances with Limousines

Steering with his right hand and sipping a martini ${ }^{1}$ with his left, Dr. Evil is pursuing James Bond in a limousine. Bond is on foot so the limousine is much faster but has a large turning radius.

The limousine is controlled by its steering wheel, and Bond can run or jump in any direction. We will set up a system of differential equations to simulate this situation and solve them with the rk-command.

Fixed parameters:
(1) limo_turning_radius
(2) limo_speed
(3) bond_speed
(4) kill_distance

## State variables:

limo_x The limousine's x-coordinate
limo_y The limousine's $y$-coordinate
limo_theta The angle the limousine makes with respect to the x-axis. Between $-\pi$ and $\pi$.
limo_steering Position of the steering wheel. Between $-\pi$ and $\pi$. It's the direction we want to go.
limo_dtheta The rate of change of limo_theta with respect to time, $t$ determined by the steering wheel and turning_radius. Since curvature is rate of change with respect to distance, $s$ and since

$$
\frac{d s}{d t}=\text { limo_speed }
$$

we get
$-\frac{1}{\text { turning_radius }} \leq \frac{\text { limo_dtheta }}{\text { limo_speed }} \leq \frac{1}{\text { turning_radius }}$
or

$$
-\frac{\text { limo_speed }}{\text { turning_radius }} \leq \text { limo_dtheta } \leq \frac{\text { limo_speed }}{\text { turning_radius }}
$$

[^32]so
limo_dtheta $=\min \left(\max \left(-\frac{\text { limo_speed }}{\text { turning_radius }}\right.\right.$, limo_steering $\left.), \frac{\text { limo_speed }}{\text { turning_radius }}\right)$
limo_dx The limousine's speed in the x-direction limo_speed $\cdot$ cos(limo_theta)
limo_dy The limousine's speed in the y-direction limo_speed $\cdot \sin ($ limo_theta)
bond_x
bond_y
bond_dx
bond_dy
The idea of this algorithm is that the limo's direction is determined by the angle limo_theta and its derivative with respect to arc-length is given by the steering wheel. We determine the angle of a line connecting the limo to bond (using the atan2-function) and increase or decrease the steering wheel accordingly (subject to the turning radius).

```
limo_speed:50;
limo_turning_radius:30;
time_step :.01;
limo_dx(limo_theta):= limo_speed *cos(limo_theta);
limo_dy(limo_theta):= limo_speed*sin(limo_theta);
normalize(theta):= block([],
if(theta>=%pi) then return (theta - 2*%pi),
if(theta<-%pi) then return (theta+2*%pi),
theta);
/* Aim straight for Bond! */
limo_steering(bond_x,bond_y,limo_x,limo_y,limo_theta)
    := block(
    [angle:atan2(bond_y-limo_y,bond_x-limo_x)],
angle-limo_theta);
/* Take turning radius into account. */
limo_dtheta(limo_steering):= block(
[lim:limo_speed/limo_turning_radius],
min(max(-lim,limo_steering),lim)
);
/* Bond's strategies */
/* Matador strategy: don't move
        unless the limo comes close! */
bond_dx(bond_x,bond_y,limo_x,limo_y,limo_theta)
    := block ([ distance],
distance=sqrt((bond_x-limo_x)^2+(limo_y-bond_y)^2),
```

```
if(distance<5) then return
    (cos(limo_theta+%pi/2)/time_step),
0);
bond_dy(bond_x,bond_y,limo_x,limo_y,limo_theta )
    := block([ distance],
distance=sqrt((bond_x-limo_x)^2+(limo_y-bond_y)^2),
if(distance<5) then return
    (sin(limo_theta+%pi/2)/time_step),
0);
/* End of Bond's strategies */
/* Run the simulation! */
pursuit:rk([
    limo_dx(limo_theta),
    limo_dy(limo_theta),
    limo_dtheta(limo_steering(bond_x,bond_y,
                            limo_x,limo_y,limo_theta)),
    bond_dx(bond_x,bond_y,limo_x,limo_y,limo_theta),
    bond_dy(bond_x,bond_y,limo_x,limo_y,limo_theta)
        ],
    [limo_x,limo_y,limo_theta,bond_x,bond_y],
    [0,0,0,10,10],
    [t,0,10,time_step]
);
```

Unfortunately, this reasonable-looking approach fails miserably ${ }^{2}$.
Suppose we abandon angles and reference a unit-vector giving the direction of the limo's motion. If $\mathbf{u}(t)$ is a unit vector then

$$
\mathbf{u} \bullet \mathbf{u}=1
$$

so

$$
\frac{d(\mathbf{u} \bullet \mathbf{u})}{d t}=2 \mathbf{u} \bullet \frac{d \mathbf{u}}{d t}=0
$$

It follows that

$$
\mathbf{u} \perp \frac{d \mathbf{u}}{d t}
$$

So the vector we pick for $d \mathbf{u} / d t$ must be perpendicular to $\mathbf{u}$. In the following program $\mathbf{u}$ is called limo_direction and $d \mathbf{u} / d t$ is bond_at ${ }_{\perp}$ (compare with definition 7.3.4 on page 110):

```
limo_speed:50;
limo_turning_radius:30;
time_step:.01;
max_angle:limo_speed/limo_turning_radius;
direction_d(bond_position,limo_position,
    limo_direction):= block(
```

[^33]```
            [bond_at,distance,dot_prod,perp,d_vect,p_comp],
            bond_at: float(bond_position-limo_position),
    distance: float(sqrt(bond_at.bond_at)),
    dot_prod: float(bond_at.limo_direction),
    perp:float(bond_at - dot_prod*limo_direction),
/* Compute the projection of bond_at
    onto limo_direction
Now compute the perpendicular vector, perp */
    perp_length: float(sqrt(perp.perp)),
    if(perp_length<.01) then return (0),
/*We're pointed in the right direction */
    /* Impose the turning-radius restrictions */
    if(perp_length >max_angle) then
    return ((max_angle/perp_length)*perp),
    perp
    );
limo_d(limo_direction):= limo_speed*limo_direction;
/* Bond's strategies */
/* Matador strategy:
    don't move unless the limo comes close! */
bond_d(bond_position,limo_position,
        limo_direction):= block(
    [bond_at:bond_position-limo_position,distance],
                distance: float(sqrt(bond_at.bond_at)),
            bond_hit:(distance<1),
            /* We're done. Bond is dead */
    if(distance < 3) then
        return (100* matrix ([-limo_direction [1,2],
            limo_direction[1,1]])),
0);
/* End of Bond's strategies */
/* Initial conditions */
limo_position :matrix ([0,0]);
bond_position : matrix ([20,-20]);
limo_direction : matrix ([ -1,0]);
path :[];
bpath:[];
bond_hit: false;
timeout:false;
/* Run the simulation! */
for t:0 step time_step unless (bond_hit or timeout)
```

```
    do(
    timeout:(t>100),
    limo_position:limo_position
        +.01*limo_d(limo_direction),
    bond_position:bond_position
        +.01*bond_d(bond_position,
            limo_position,limo_direction),
    limo_direction:limo_direction
        +.01*direction_d(bond_position,
            limo_position,limo_direction),
    /* Record the limo's location:
        place the limo's coords
        at the end of its path.*/
    path:endcons([limo_position[1,1],
                            limo_position[1,2]], path),
    /* Normalize limo_direction
        so it remains a unit-vector */
    limo_direction:
    float(limo_direction
                            /sqrt(limo_direction.limo_direction)),
    /* Record Bond's location:
        place Bond's coords at the
        end of his path.*/
    bpath: endcons([bond_position [1,1],
                bond_position[1,2]],bpath)
        ); /* End of for-loop */
/* Watch the dance! */
plot2d([[discrete, path],[discrete,bpath]],
    [style,[lines ,1],[points,1]],
    [legend,"Limo","Bond"]);
```

Unfortunately, the rk-command requires its arguments to be real scalars (argh!) and fails silently if they aren't.

We dispense with the rk-command and use a finite-difference approximation to derivatives (see Euler's method, equation 4.1.5 on page 47)

$$
\frac{d \text { limo_direction }}{d t} \sim \frac{\Delta \text { limo_direction }}{\Delta t}
$$

which becomes more accurate the smaller $\Delta t$ is. We pick $\Delta t=.01$. Since this is only an approximate derivative, limo_direction will grow with each iteration of the for-loop. We reset it to being a unit-vector via

```
limo_direction:
    float(limo_direction
        /sqrt(limo_direction.limo_direction)),
```

Figure 11.1.1. Turning radius=30

Take note of the command

```
/* Record the limo's location:
    place the limo's coords
    at the end of its path.*/
path:endcons([limo_position [1,1],
    limo_position [1,2]], path),
```

for keeping a record of the limo's position and compare to Note 7.1.1 on page 100.

If we run the code as given above, we get figure 11.1.1, which shows that it's easy to evade a limo with a large turning radius that is close by just stand in one spot!

If we set the turning radius to 10 , we get figure 11.1.2 on the next page, where Bond has to jump around a bit.

Note that this program works in $n$-dimensions, whereas the program using angles would only work in two, at best ${ }^{3}$.

If Bond stands far away ( $x=100$, for instance) even a large turning radius limo manages to catch him - see figure 11.1.3 on the facing page. This suggests a strategy to use when the turning radius is large.

Note that the limo starts by facing away from Bond. This is the initial condition

```
limo_direction : matrix ([ - 1,0\(]\) );
```

Something strange happens if Bond starts out on the positive $x$-axis, say at $(10,0)$. We get the plot in figure 11.1.4 on page 180, where the limo frantically runs away from Bond! This is what is called the Gimbel Problem: certain angles cause algorithms to lock up and execute incorrectly. This problem

[^34]

Figure 11.1.2. Turning radius=10

Figure 11.1.3. Bond far away
occurs because we assume that, if perp=0, we must be facing Bond whereas we might be facing away from him.

Equation 7.3.1 on page 109 suggests the solution: if dot_prod $>0$, we are facing Bond, and if dot_prod $<0$, we are facing away. We amend the limo-code by replacing

```
    perp_length: float(sqrt(perp.perp)),
    if(perp_length<.01) then return (0),
/*We're pointed in the right direction */
```

with

```
perp_length: float(sqrt(perp.perp)),
if ((perp_length <.01) and (dot_prod >0))
```

Figure 11.1.4. Gimbel problem

Figure 11.1.5. Solution to the Gimbel Problem
then return (0),
/*We're pointed in the right direction */
if (perp_length $<.01$ ) then return
(matrix ([-limo_direction [1,2],
limo_direction [1, 1]])),
/* Jump sideways, so we're no longer lined up with Bond */
and this gives us figure 11.1.5.

## ExERCISES.

1. Why does the initial program that uses angles and atan 2 fail?
2. Why did we need the timeout logical variable?
3. Dr. Evil is afraid of spilling his martini if he makes a left turn ${ }^{4}$. Rewrite the limo program so it only makes right turns.
4. Rewrite the limo program so it is capable of hitting Bond even if its turning radius is large and Bond is nearby. Hint: If Bond is nearby, put the limo into back-off mode and drive away. When it's far enough away, put it back into attack mode.
5. In the program given, Bond always jumps in a direction perpendicular to the direction of the limo. Experiment with other angles.
6. Notice that Bond never gets tired and always jumps a huge distance (100). Rewrite the program so Bond get tired after each jump, and the distance jumped decreases until he is unable to jump at all.

### 11.2. Rock, Paper, Rocket

In this section we consider the opposite problem from the last:
Is it possible to hit a fast object with a slow one?
Clearly, if the slow object merely chases the fast one, it will miss. We suppose the fast object is headed to a target and the slow one starts out near the target. We'll begin by assuming that the fast object heads in a straight line to the target.

We begin by coding the main loop and the rocket's equations of motion:

```
rocket_speed:100;
rocket_start:matrix ([100,3]);
target_location:matrix ([0,0]);
time_step:.01;
timeout:false;
target_hit:false;
rocket_location:copymatrix(rocket_start);
rocket_dir:matrix ([1,0]);
rocket_path:[];
    rocket_unit(rocket_location,target_location):= block(
    [vector_to_target,dist_to_target],
    vector_to_target:target_location
            - rocket_location,
    dist_to_target: float(sqrt(vector_to_target
```

[^35]```
            .vector_to_target)),
            if(dist_to_target <1.0) then
            return(matrix ([0,0])),
                float(vector_to_target/dist_to_target)
                );
for t:0 step time_step unless (timeout or target_hit)
    do (
        timeout:t>100,
        rocket_dir:rocket_unit(rocket_location,
        target_location),
    target_hit:rocket_dir.rocket_dir <.5,
        rocket_location:rocket_location
        +time_step*rocket_speed*rocket_dir,
        rocket_path:endcons([rocket_location [1,1],
                                rocket_location[1,2]],rocket_path)
    );
plot2d([discrete, rocket_path],
    [style ,[lines ,1],[points,1]]);
```

Now we add the code for the rock. We'll begin by using the simplest code possible: simply head in the direction of the rocket ${ }^{5}$. We have

```
rock_unit(rocket_location,target_location ,
        rock_location ):= block(
    [vector_to_rocket,dist_to_rocket],
        vector_to_rocket:rocket_location
        - rock_location,
    dist_to_rocket: float(sqrt(vector_to_rocket
        .vector_to_rocket)),
        if(dist_to_rocket <1.0) then
        return(matrix ([0,0])),
        float(vector_to_rocket/dist_to_rocket)
        );
```

and combining it with the previous code gives

```
rocket_speed:100;
rocket_start:matrix ([100,3]);
target_location:matrix ([0,0]);
time_step:.01;
timeout:false;
target_hit:false;
rocket_hit:false;
rocket_location:copymatrix(rocket_start);
rocket_dir:matrix ([1,0]);
```

${ }^{5}$ So our "rock" can be steered!

```
rock_speed:10;
rock_offset:matrix ([5,5]);
rocket_path:[];
rock_location:target_location+rock_offset;
rock_path:[];
rocket_unit(rocket_location, target_location ):= block(
    [vector_to_target,dist_to_target],
    vector_to_target:target_location
                - rocket_location,
        dist_to_target:float(sqrt(vector_to_target
        .vector_to_target)),
    if(dist_to_target < 1.0) then
        return(matrix ([0,0])),
    float(vector_to_target/dist_to_target)
    );
rock_unit(rocket_location,
                rock_location):= block(
    [vector_to_rocket,dist_to_rocket],
        vector_to_rocket:rocket_location
                - rock_location,
            dist_to_rocket:float (sqrt(vector_to_rocket
                .vector_to_rocket)),
        if(dist_to_rocket <1.0) then
            return(matrix ([0,0])),
        float(vector_to_rocket/dist_to_rocket)
        );
for t:0 step time_step
        unless (timeout or target_hit or rocket_hit)
    do (
        timeout:t>100,
        rocket_dir:rocket_unit(rocket_location,
        target_location),
        target_hit:rocket_dir.rocket_dir< .5,
        rock_dir:rock_unit(rocket_location,
        rock_location),
        rocket_hit:rock_dir.rock_dir<.5,
        rocket_location:rocket_location
        +time_step*rocket_speed*rocket_dir ,
        rock_location:rock_location
            +time_step*rock_speed*rock_dir,
        rocket_path:endcons([rocket_location [1,1],
                                    rocket_location [1,2]],
                    rocket_path),
        rock_path:endcons([rock_location [1,1],
```

FIGURE 11.2.1. Naive pursuit algorithm

```
    rock_location[1,2]],rock_path)
        );
plot2d([[ discrete, rocket_path],[discrete, rock_path ]],
    [style,[lines,1],[points,1]]);
```

This produces the plot in figure 11.2.1. Clearly, we have failed to stop the rocket! If we increase the rock speed to 30 , we get the plot in figure

As it nears the rocket, the rock simply chases it and will always lose.
We will try a slightly more sophisticated algorithm:
(1) Determine how far away the rocket is,
(2) Determine how long it would take to reach that point (at the speed the rock travels),
(3) Estimate the possible future location of the rocket at that time, using the rocket's direction,
(4) Aim for that location instead of the rocket's present location.

```
/* Predictive Rocket vs. Rock program */
rocket_speed:100;
rocket_start:matrix([100,3]);
target_location : matrix ([0,0]);
time_step:.01;
timeout:false;
target_hit:false;
rocket_hit:false;
rocket_location:copymatrix(rocket_start);
rocket_dir:matrix ([1,0]);
```

Figure 11.2.2. Rock speed 30

```
rock_speed:30;
rock_offset:matrix ([5,5]);
rocket_path:[];
/* The rock is not located at the target,
    but offset from it */
rock_location:target_location+rock_offset;
rock_path:[];
/* The rocket's direction of travel */
    rocket_unit(rocket_location,
        target_location):= block(
            [vector_to_target,dist_to_target],
            vector_to_target:target_location
                - rocket_location,
                dist_to_target: float(sqrt(vector_to_target
            .vector_to_target)),
                if(dist_to_target < 1.0) then
            return(matrix ([0,0])),
        float(vector_to_target/dist_to_target)
        );
/*The rock's direction of travel*/
        rock_unit(rocket_location,rock_location,
        rocket_dir):= block(
        [vector_to_rocket,dist_to_rocket,
            rocket_future,vector_to_future,
```

```
        dist_to_future],
        vector_to_rocket:rocket_location
        - rock_location,
        dist_to_rock: float(sqrt(vector_to_rocket
        .vector_to_rocket)),
        if(dist_to_rock <1.0) then
        return(matrix([0,0])),
/* The rocket's predicted future position */
        rocket_future:rocket_location+
            rocket_dir*rocket_speed/rock_speed,
        vector_to_future:rocket_future
            -rock_location,
        dist_to_future:
            sqrt(vector_to_future.vector_to_future),
/* Aim at the future position! */
        float(vector_to_future/dist_to_future)
        );
for t:0 step time_step
        unless (timeout or target_hit or rocket_hit)
    do (
        timeout:t>100,
        rocket_dir:rocket_unit(rocket_location,
            target_location),
        target_hit:rocket_dir.rocket_dir <.1,
        rock_dir:rock_unit(rocket_location,
            rock_location,rocket_dir),
        rocket_hit:rock_dir.rock_dir <.1,
        if(rocket_hit) then print("Rocket_hit"),
        rocket_location:rocket_location
        +time_step*rocket_speed*rocket_dir,
        rock_location:rock_location
            +time_step *rock_speed *rock_dir,
        rocket_path:endcons([rocket_location[1,1],
                        rocket_location[1,2]],
            rocket_path),
        rock_path:endcons([rock_location [1,1],
                        rock_location [1,2]],rock_path)
        );
plot2d([[ discrete, rocket_path],[discrete,rock_path ]],
    [style ,[lines ,1],[ points,1]],
    [legend," Rocket","Rock" ]);
```

We will also print out "Rocket hit" if this happens. We get the plot in figure 11.2.3 on the next page, the "Rocket hit" phrase is printed, and the rocket doesn't get within 20 units of the target, even though it is traveling more than 3 times the rock's speed!

FIGURE 11.2.3. Predictive algorithm with rock speed 30

## EXERCISES.

1. Experiment with the predictive program and determine the minimum speed the rock must be traveling to guarantee that the rocket does not get within 10 distance-units of the target.
2. Experiment with different offsets of the rock-launch-point.
3. Try the program where the rocket follows a curved path rather than a straight line.
4. Consider possible improvements to the predictive algorithm and program them. Our program uses the first derivative of the rocket motion (its tangent vector). Consider how one could estimate its second derivative and use that (and the first) to estimate its future location. Hint: consider how much the rocket's unit-vector changes between a given call to the rock-routine and the previous call.
5. Suppose the rocket has random fluctuations in its direction to try to confuse the rock. These fluctuations must decrease to 0 as the rocket approaches the target, or it won't have a chance of hitting the target. Program this!

## CHAPTER 12

## Special Functions

"Certain functions appear so often that it is convenient to give them names. These are collectively called special functions. There are many examples and no single way of looking at them can illuminate all examples or even all the important properties of a single example of a special function."

- Richard Askey.

### 12.1. The Gamma Function

In an attempt to define factorials over non-integers, Bernoulli defined the function

$$
\begin{equation*}
\Gamma(z)=\int_{0}^{\infty} e^{-t} z^{t-1} d t \quad \text { for } \Re(z)>0 \tag{12.1.1}
\end{equation*}
$$

Integration by parts shows that

$$
\begin{equation*}
\Gamma(z+1)=z \Gamma(z) \tag{12.1.2}
\end{equation*}
$$

Since $\Gamma(1)=1$, an easy induction shows that

$$
\Gamma(n)=(n-1)!
$$

for $n$ a positive integer.
Daniel Bernoulli (1700-1782) was a Swiss mathematician and physicist and was one of the many prominent mathematicians in the Bernoulli family from Basel. He is particularly remembered for his applications of mathematics to mechanics, especially fluid mechanics, and for his pioneering work in probability and statistics. His name is commemorated in the Bernoulli's principle, a particular example of the conservation of energy, which describes the mathematics of the mechanism underlying the operation of two important technologies of the 20th century: the carburetor and the airplane wing.

Maxima implements the $\Gamma$-function via the gamma-command. For instance

```
map('gamma,[1,2,3,4,5,6,7,8,9]);
```

returns

$$
[1,1,2,6,24,120,720,5040,40320]
$$

We can $\operatorname{plot} \Gamma(x)$ on the real line via

```
plot2d(gamma(x),[x,-5,5],[y,-10,10],[style ,
[lines,2,5]],[grid,10,20]);
```

Figure 12.1.1. The $\Gamma$-function
to get figure 12.1.1.
We also have the Euler Reflection equation

$$
\Gamma(1-z) \Gamma(z)=\frac{\pi}{\sin (\pi z)}
$$

from which it is easy to derive the famous equation

$$
\Gamma(1 / 2)=\sqrt{\pi}
$$

or

$$
\left(-\frac{1}{2}\right)!=\sqrt{\pi}
$$

and

$$
\frac{1}{2}!=\frac{\sqrt{\pi}}{2}
$$

Equation 12.1.2 on the previous page allows us to extend the gamma function over the whole complex plane, except for zero and negative integers via

$$
\Gamma(z)=\frac{\Gamma(z+1)}{z}
$$

and the Euler reflection formula:

$$
\begin{equation*}
\Gamma(z) \cdot \Gamma(1-z)=\frac{\pi}{\sin (\pi z)} \tag{12.1.3}
\end{equation*}
$$

— see [1, chapter 5].
The command

```
plot3d (cabs(gamma(u+%i*v)), [u, -5, 5], [v, -5, 5],
[z,0,20],[xlabel,"Reals"],[ylabel,"Imag"],
[grid,100,100]);
```

Figure 12.1.2. Plot of $|\Gamma(z)|$
produces figure 12.1.2.
Maxima also "knows" other functions of the gamma-function that are used in number-theory.
$\triangleright$ bffac (expr, n) - a bigfloat version of the factorial function (i.e., gamma(expr+1))
$\triangleright \log _{\text {_gamma(z) }}$ - self-explanatory.
$\triangleright$ gamma_incomplete_lower $(\mathrm{a}, \mathrm{z})=\int_{0}^{z} e^{-t} a^{t-1} d t$
$\triangleright$ gamma_incomplete $(\mathrm{a}, \mathrm{z})=\int_{z}^{\infty} e^{-t} a^{t-1} d t$
$\triangleright$ gamma_incomplete_regularized $(\mathrm{a}, \mathrm{z})$ =gamma_incomplete $(a, z) /$ gamma(a)
$\Delta$ beta $(\mathrm{a}, \mathrm{b})$ - The beta function is defined as gamma(a)*gamma(b)/gamma(a+b)
$\triangleright \operatorname{psi}[\mathrm{n}](\mathrm{x})$ - The derivative of $\log (\operatorname{gamma}(\mathrm{x}))$ of order $\mathrm{n}+1$. Thus, $\operatorname{psi}[0](x)$ is the first derivative, $\operatorname{psi}[1](x)$ is the second derivative, etc.

## EXERCISES.

1. If $x$ is a number and $m$ is a positive integer, recall the falling factorial or Pochhammer symbols $(x)_{m}$ from chapter 8 on page 143 defined by

$$
(x)_{m}=x \cdot(x-1) \cdots(x-m+1)
$$

Extend this definition to all complex values of $x$ and $m$ using the gamma function. Note that, if $x$ and $m$ are integers and $m>x$, then we get a factor $(x-x)=0$ so the result is 0 .
2. Write a Maxima function to compute falling factorials $(x)_{n}$ for all complex values of $x$ and $n$.
3. A simple induction shows that for any positive integer, $k$,

$$
\frac{d^{k} x^{n}}{d x^{k}}=n(n-1) \cdots(n-k+1) x^{n-k}
$$

Extend this to arbitrary complex values of $k$, so one could define (for instance)

$$
\frac{d^{1 / 2} x}{d x^{1 / 2}}
$$

## 4. Compute

$$
\frac{d^{1 / 2} e^{x}}{d x^{1 / 2}}
$$

by computing that for each term of its Taylor series. Plot this function and $e^{x}$.

### 12.2. Elliptic integrals and elliptic functions

Elliptic integrals and functions have a long and complex history that impinges on numerous other areas of mathematics, including complex analysis, number theory, and algebraic geometry.

The general elliptic integral is anything of the form

$$
\int_{c}^{x} R(t, \sqrt{P(t)}) d t
$$

where $c$ is a constant, $R(u, v)$ is a rational function, and $P(t)$ is a polynomial of degree 3 or 4 with no repeated roots. Any elliptic integral can be transformed into a linear combination of an integral of a rational function and Legendre elliptic integrals of the first, second, and third kinds - see [48].

Carl Gustav Jacob Jacobi (1804-1851) was a German mathematician who made fundamental contributions to elliptic functions, dynamics, differential equations, determinants, and number theory. His name is occasionally written as Carolus Gustavus Iacobus Iacobi in his Latin books, and his first name is sometimes given as Karl.

We will focus on elliptic integrals and Jacobi's elliptic functions, which initially arose in in an effort to parametrize the arc-length of an ellipse. The incomplete elliptic integral of the first kind is

$$
F(x, k)=\int_{0}^{x} \frac{d t}{\sqrt{\left(1-t^{2}\right)\left(1-k^{2} t^{2}\right)}}=\int_{0}^{\phi} \frac{d t}{\sqrt{1-k^{2} \sin ^{2} t}}
$$

where $0 \leq x \leq 1,0 \leq \phi \leq \pi / 2$, and the quantity $0 \leq k \leq 1$ is called the modulus of the elliptic integral. The complete elliptic integral simply has $x=1$ ( or $\phi=\pi / 2$ ).

Figure 12.2.1. Pendulum

The incomplete elliptic integral of the first kind is also sometimes written

$$
F(\phi, k)=\int_{0}^{\sin \phi} \frac{d t}{\sqrt{\left(1-t^{2}\right)\left(1-k^{2} t^{2}\right)}}
$$

This is the form Maxima implements:

```
elliptic_f(phi, m)
```

where $m=k^{2}$.
If we type

```
elliptic_f(x, 0)
```

## we get

```
X
```

and if we type

```
elliptic_f(x, 1)
```

we get

$$
\log \left(\tan \left(\frac{x}{2}+\frac{\pi}{4}\right)\right)
$$

EXAMPLE 12.2.1. We will discuss an application of the the elliptic integral of the first kind. Consider the pendulum in figure 12.2.1

The tangential force on the bob perpendicular to the rod is $-m g \sin \theta$, where $m$ is the bob's mass and $g$ is the acceleration of gravity. This force is also equal to

$$
m \frac{d v_{T}}{d t}=m \frac{d}{d t}\left(R \frac{d \theta}{d t}\right)=m R \frac{d^{2} \theta}{d t^{2}}
$$

Equating these quantities gives

$$
m R \frac{d^{2} \theta}{d t^{2}}=-m g \sin \theta
$$

so the equation of motion becomes

$$
\begin{equation*}
\frac{d^{2} \theta}{d t^{2}}+\frac{g}{R} \sin \theta=0 \tag{12.2.1}
\end{equation*}
$$

Compare this with equation 5.3 .2 on page 82 for a harmonic oscillator and figure 5.3.1 on page 82. The sine-term adds considerable complexity.

Now we multiply by $d \theta / d t$ to get

$$
\left(\frac{d^{2} \theta}{d t^{2}}\right) \frac{d \theta}{d t}+\frac{g}{R} \sin \theta \frac{d \theta}{d t}=0
$$

and integrate with respect to $t$ to get

$$
\frac{1}{2}\left(\frac{d \theta}{d t}\right)^{2}-\frac{g}{R} \cos \theta=C
$$

where $C$ is the constant of integration. If we set $d \theta / d t=0$, we get $C=$ $-\frac{g}{R} \cos \theta$, which means $\theta=\theta_{0}$, the pendulum's initial angle. Our equation becomes

$$
\begin{aligned}
\frac{d \theta}{d t} & =\sqrt{2\left(\frac{g}{R} \cos \theta-\frac{g}{R} \cos \theta_{0}\right)} \\
& =\sqrt{\frac{2 g}{R}} \sqrt{\cos \theta-\cos \theta_{0}}
\end{aligned}
$$

Now we apply the identity

$$
\cos \theta=1-2 \sin ^{2}\left(\frac{\theta}{2}\right)
$$

to get

$$
\frac{d \theta}{d t}=2 \sqrt{\frac{g}{R}} \sqrt{\sin ^{2}\left(\frac{\theta_{0}}{2}\right)-\sin ^{2}\left(\frac{\theta}{2}\right)}
$$

so

$$
\frac{d t}{d \theta}=\frac{1}{2} \sqrt{\frac{R}{g}} \frac{1}{\sqrt{k^{2}-\sin ^{2}\left(\frac{\theta}{2}\right)}}
$$

where $k=\sin \left(\theta_{0} / 2\right)$. The complete period of the pendulum is

$$
\begin{equation*}
T=4 \cdot \frac{1}{2} \sqrt{\frac{R}{g}} \cdot \int_{0}^{\theta_{0}} \frac{d \theta}{\sqrt{k^{2}-\sin ^{2}\left(\frac{\theta}{2}\right)}} \tag{12.2.2}
\end{equation*}
$$

Now we do a $u$-substitution, setting $\sin (\theta / 2)=k \sin (u)$, which implies that

$$
\cos \left(\frac{\theta}{2}\right) \frac{d \theta}{2}=k \cos (u) d u
$$

or

$$
\begin{align*}
d \theta & =\frac{2 k \cos (u)}{\cos \left(\frac{\theta}{2}\right)} d u=\frac{2 k \sqrt{1-\sin ^{2}(u)}}{\sqrt{1-k^{2} \sin ^{2}(u)}} d u \\
& =\frac{2 \sqrt{k^{2}-\sin ^{2}(\theta / 2)}}{\sqrt{1-k^{2} \sin ^{2}(u)}} d u \tag{12.2.3}
\end{align*}
$$

Now we plug equation 12.2.3 on the preceding page into equation 12.2.2 on the facing page to get the complete elliptic integral of the first kind

$$
\begin{equation*}
T=4 \sqrt{\frac{R}{g}} \cdot \int_{0}^{\pi / 2} \frac{d u}{\sqrt{1-k^{2} \sin ^{2}(u)}} \tag{12.2.4}
\end{equation*}
$$

where we note that when $\theta=\theta_{0}, k=\sin \left(\theta_{0} / 2\right)=\sin \left(\theta_{0} / 2\right) \sin (u)$, so $\sin (u)=1$, and $u=\pi / 2$.

The inverse of the elliptic integral of the first kind is the elliptic function $\operatorname{sn}(x, k)$, a generalization of the sine-function. Indeed, $\operatorname{sn}(x, 0)=\sin x$. These were first studied by Jacobi.

Maxima implements these things via
jacobi_sn(u, m);
where $m=k^{2}$.
See figure 12.2.2 on the next page ${ }^{1}$, which is a plot of the Jacobi ellipse

$$
x^{2}+\frac{y^{2}}{b^{2}}=1
$$

with $b$ real. The quantities $m$ and $b$ are related via

$$
b^{2}=\frac{1}{m}
$$

The twelve Jacobi functions, $\mathbf{v w}(\mathrm{u}, \mathrm{m})$, are shown, where $w, v=s, c, d, n$ and any function of the form $\mathbf{w w}$ is defined to be 1 for the sake of completeness. In general

$$
\mathbf{w} \mathbf{v}(u, m)=\frac{1}{\mathbf{v} \mathbf{w}(u, m)}
$$

In figure 12.2.2 on the following page note that

$$
\begin{aligned}
\sin \phi & =\operatorname{sn}(u, m) \\
\cos \phi & =\operatorname{cn}(u, m)
\end{aligned}
$$

where $u$ is arc-length along the ellipse (from the point $(1,0)$ ). This implies that

$$
\operatorname{sn}^{2}(u, m)+\mathrm{cn}^{2}(u, m)=1
$$

for all $u, m$.
Maxima "knows" some properties of these functions:
jacobi_sn(u, 0);
produces $\sin (u)$ and typing
jacobi_sn (u, 1);
produces $\tanh (u)$.
The command

$$
\text { plot2d(jacobi_sn }(x, .9),[x, 0,10],[\text { style , [lines , } 2,5][) ;
$$

[^36]

Figure 12.2.2. Jacobi functions

Figure 12.2.3. Plot of $\operatorname{sn}(x, .9)$
produces the plot in figure 12.2.3.
Notice that the graph of $\operatorname{sn}(x, .9)$ looks like a sine curve that has been "rounded".

Figure 12.2.4 on the facing page shows the complementary function.
Other elliptic functions that Maxima implements include

```
jacobi_dn(u, m);
jacobi_ns(u,m)=1/jacobi_sn (u,m);
jacobi_sc(u,m)=jacobi_sn (u,m)/jacobi_cn(u,m);
jacobi_cs(u,m)=jacobi_cn(u,m)/jacobi_sn (u,m);
jacobi_nd(u,m)=1/jacobi_dn(u, m);
```

Figure 12.2.4. Plot of $\mathrm{cn}(x, .9)$

```
jacobi_ds(u,m)=jacobi_dn(u, m)/jacobi_sn (u,m);
jacobi_dc(u,m)=jacobi_dn (u,m)/jacobi_cs (u,m);
```

Maxima also implements the inverses of all of these functions, although the inverse of $\operatorname{sn}(u, m)$ is technically the elliptic integral of the first kind. Their names are the word 'inverse_' followed by the Maxima name of the function.

Now we will consider the elliptic integrals of the second

$$
E(\phi, m)=\int_{0}^{\phi} \sqrt{1-m \sin ^{2} \theta} d \theta=\int_{0}^{\sin \phi} \frac{\sqrt{1-m t^{2}}}{\sqrt{1-t^{2}}} d t
$$

and third kinds

$$
\Pi(n, \varphi, m)=\int_{0}^{\sin \varphi} \frac{d t}{\left(1-n t^{2}\right) \sqrt{(1-m t)^{2}\left(1-t^{2}\right)}}
$$

The number $n$ is called the characteristic and can take on any value. These are coded into Maxima, respectively, as

```
elliptic_e (phi, m)
```

and
elliptic_pi (n, phi, m)

## ExERCISES.

1. Using elliptic functions, give a parametric plot of an ellipse with $m=.9$. Hint: Closely examine figure 12.2.2 on page 196.
2. What's the period of a pendulum with $R=1$ foot, $g=32$ feet $/$ second $^{2}$, and a starting angle of $45^{\circ}$ ?
3. In a pendulum, as the starting angle approaches $180^{\circ}$ the period approaches $\infty$. What is going on?

### 12.3. Bessel functions

Bessel functions were first defined by Daniel Bernoulli and generalized by Friedrich Bessel as solutions to Bessel's differential equation

$$
\begin{equation*}
x^{2} \frac{d^{2} y}{d x^{2}}+x \frac{d y}{d x}+\left(x^{2}-\alpha^{2}\right) y=0 \tag{12.3.1}
\end{equation*}
$$

for a complex number, $\alpha$, which is called the order of the Bessel function. The most significant values for $\alpha$ are integer and half-integer values. The integer values arise from converting the two-dimensional wave equation (see section 4.6 .4 on page 70 ) to polar or cylindrical coordinates, and the half-integer values arise from converting it to spherical coordinates.

The general solution to equation 12.3.1 is

$$
A J_{\alpha}(x)+B Y_{\alpha}(x)
$$

where $J_{\alpha}(x)$ and $Y_{\alpha}(x)$ are called, respectively, Bessel functions of the first and second kind.

Friedrich Wilhelm Bessel (1784-1846) was a German astronomer, mathematician, and physicist. He was the first astronomer who determined reliable values for the distance from the sun to another star by the method of parallax. Certain important mathematical functions were named Bessel functions after Bessel's death, though they had originally been discovered by Daniel Bernoulli before being generalized by Bessel.

To see how Bessel's equation arises, we convert the wave equation into polar coordinates.

In polar coordinates, $(r, \theta)$, we have

$$
\frac{\partial^{2} \psi}{\partial x^{2}}+\frac{\partial^{2} \psi}{\partial y^{2}}=\frac{1}{r} \frac{\partial}{\partial r}\left(r \frac{\partial \psi}{\partial r}\right)+\frac{1}{r^{2}} \frac{\partial^{2} \psi}{\partial \theta^{2}}=\frac{1}{c^{2}} \frac{\partial^{2} \psi}{\partial t^{2}}
$$

We write $\psi(r, \theta, t)=\tau(t) \Phi(r, \theta)$ to get

$$
\tau \frac{1}{r} \frac{\partial}{\partial r}\left(r \frac{\partial \Phi}{\partial r}\right)+\tau \frac{1}{r^{2}} \frac{\partial^{2} \Phi}{\partial \theta^{2}}=\Phi \frac{1}{c^{2}} \frac{\partial^{2} \tau}{\partial t^{2}}
$$

or

$$
\frac{1}{\Phi r} \frac{\partial}{\partial r}\left(r \frac{\partial \Phi}{\partial r}\right)+\frac{1}{\Phi r^{2}} \frac{\partial^{2} \Phi}{\partial \theta^{2}}=\frac{1}{\tau c^{2}} \frac{\partial^{2} \tau}{\partial t^{2}}=-\lambda
$$

where $\lambda$ is a constant (the only way a function of $t$ could equal a function of other, independent, variables). So we get

$$
\begin{aligned}
\frac{d^{2} \tau}{d t^{2}}+\lambda \tau & =0 \\
\frac{1}{r} \frac{\partial}{\partial r}\left(r \frac{\partial \Phi}{\partial r}\right)+\frac{1}{r^{2}} \frac{\partial^{2} \Phi}{\partial \theta^{2}}+\lambda \Phi & =0
\end{aligned}
$$

Now, we write $\Phi(r, \theta)=R(r) \Xi(\theta)$ and get

$$
\Xi \frac{1}{r} \frac{\partial}{\partial r}\left(r \frac{\partial R}{\partial r}\right)+R \frac{1}{r^{2}} \frac{\partial^{2} \Xi}{\partial \theta^{2}}+\lambda R \Xi=0
$$

and dividing by $R(r) \Xi(\theta)$ and multiplying by $r^{2}$ gives

$$
\frac{r}{R} \frac{\partial}{\partial r}\left(r \frac{\partial R}{\partial r}\right)+\frac{1}{\Xi} \frac{\partial^{2} \Xi}{\partial \theta^{2}}+\lambda r^{2}=0
$$

or

$$
\frac{r}{R} \frac{\partial}{\partial r}\left(r \frac{\partial R}{\partial r}\right)+\lambda r^{2}=-\frac{1}{\Xi} \frac{\partial^{2} \Xi}{\partial \theta^{2}}
$$

Again, we are faced with a situation where a function of one variable is equal to one of another, so they both equal the same constant

$$
\begin{aligned}
\frac{r}{R} \frac{d}{d r}\left(r \frac{d R}{d r}\right)+\lambda r^{2} & =\kappa \\
\frac{1}{\Xi} \frac{d^{2} \Xi}{d \theta^{2}} & =-\kappa
\end{aligned}
$$

The top equation is equal to

$$
r^{2} \frac{d^{2} R}{d r^{2}}+r \frac{d R}{d r}+R \lambda r^{2}=\kappa R
$$

or

$$
r^{2} \frac{d^{2} R}{d r^{2}}+r \frac{d R}{d r}+R\left(\lambda r^{2}-\kappa\right)=0
$$

A change of scale ( $\bar{r}=r \sqrt{\lambda}$ ) allows us to get rid of $\lambda$, and we get Bessel's differential equation. Maxima implements Bessel functions. The first kind is called bessel_j $\mathbf{j}(v, z)$ with mathematical notation $J_{v}(z)$. It can be defined via

$$
J_{v}(z)=\sum_{k=0}^{\infty} \frac{(-1)^{k} 2^{v-2 k} z^{v+2 k}}{k!\Gamma(v+k+1)}
$$

or an integral representation

$$
J_{v}(z)=\frac{1}{\pi} \int_{0}^{\pi} \cos (v t-z \sin t) d t
$$

If we type

```
plot2d([ bessel_j (0,x),bessel_j (1,x),bessel_j (2,x)],
[x,0,10],[ style ,[lines ,2,5],
[points,1,4,5],[lines ,2,1]]);
```

Figure 12.3.1. First three Bessel J-functions

Figure 12.3.2. First three Bessel Y-functions
gives us figure 12.3.1.
The second kind is called bessel_y $(v, z)$ with mathematical notation $Y_{v}(z)$. These functions have a singularity at 0 , going to $-\infty$. We can graph them
plot2d ([ bessel_y (0, x) , bessel_y $(1, x)$, bessel_y $(2, x)]$, [x,.1,10],[y,-4,1],[ style ,[lines ,2,5], [points, $1,4,5],[$ lines , 2,1$]$ ]);
to get figure 12.3.2.
These are related to the $J$-Bessel functions via the equation

$$
Y_{k}(z)=\frac{\cos (\pi k) J_{k}(z)-J_{-k}(z)}{\sin (\pi k)}
$$

when $k$ is not an integer. When it is (an integer), take the limit as $k$ approaches its integer value.

Bessel functions are used for
$\triangleright$ Electromagnetic waves in a cylindrical waveguide.
$\triangleright$ Pressure amplitudes of inviscid rotational flows.
$\triangleright$ Heat conduction in a cylindrical object.
$\triangleright$ Modes of vibration of a thin circular or annular acoustic membrane or thicker plates such as sheet metal.
$\triangleright$ Solutions to the radial Schrödinger equation (in spherical and cylindrical coordinates) for a free particle.
$\triangleright$ Solving for patterns of acoustical radiation.
$\triangleright$ Frequency-dependent friction in circular pipelines.
$\triangleright$ Dynamics of floating bodies.
$\triangleright$ Diffraction from helical objects, including DNA.
$\triangleright$ Probability density function of product of two normally distributed random variables.

### 12.4. Airy functions

The two linearly independent Airy functions $\operatorname{Ai}(x)$ and $\operatorname{Bi}(x)$ are solutions to Airy's differential equation

$$
\frac{d^{2} y}{d x^{2}}-x y=0
$$

These functions have the interesting property that they switch from being oscillatory when $x<0$ to being exponential when $x>0$. Their Maxima definitions are, respectively,

```
airy_ai(x)
```

and

```
airy_bi(x)
```

Their "switching" behavior is clear from figure 12.4.1 on the following page.

For real values of $x$ we have the integral formulas

$$
\begin{aligned}
& \operatorname{Ai}(x)=\frac{1}{\pi} \int_{0}^{\infty} \cos \left(\frac{t^{3}}{3}+x t\right) d t \\
& \operatorname{Bi}(x)=\frac{1}{\pi} \int_{0}^{\infty}\left(e^{-t^{3} / 3+x t}+\sin \left(\frac{t^{3}}{3}+x t\right)\right) d t
\end{aligned}
$$

Maxima also implements first derivatives of the Airy functions

```
airy_dai(x)
```

and

```
airy_dbi(x)
```

Figure 12.4.1. The Airy Functions

The Airy function is the solution to the time-independent Schrödinger equation for a particle confined within a triangular potential well and for a particle in a one-dimensional constant force field.

Sir George Biddell Airy (1801-1892) was an English mathematician and astronomer, and the seventh Astronomer Royal from 1835 to 1881. His many achievements include work on planetary orbits, measuring the mean density of the Earth, a method of solution of two-dimensional problems in solid mechanics and, in his role as Astronomer Royal, establishing Greenwich as the location of the prime meridian.

Forming the Fourier transform of Airy's differential equation gives us the Fourier transform of $\operatorname{Ai}(x)$ :

$$
\mathcal{F}(\mathrm{Ai}(x))(s)=e^{(2 \pi s)^{3} / 3}
$$

### 12.5. Logarithmic and exponential integrals

We begin with the logarithmic integral, defined via

$$
\begin{equation*}
\operatorname{li}(x)=\int_{0}^{x} \frac{d t}{\log t} \tag{12.5.1}
\end{equation*}
$$

The Maxima command for this is

```
expintegral_li(x)
```

The command

```
plot2d(expintegral_1i(x),[x,0,5],[y, -5,5]);
```

produces the plot in figure 12.5 . 1 on the next page.

Figure 12.5.1. The li-function

The function $1 / \log (x)$ has a singularity at $x=1$, in which case, we interpret equation 12.5.1 on the facing page as the Cauchy principal value:

$$
\begin{equation*}
\operatorname{li}(x)=\lim _{\epsilon \rightarrow 0^{+}}\left(\int_{0}^{1-\epsilon} \frac{d t}{\log t}+\int_{1+\epsilon}^{x} \frac{d t}{\log t}\right) \tag{12.5.2}
\end{equation*}
$$

whenever $x>1$.
We also have

$$
\operatorname{Li}(x)=\int_{2}^{x} \frac{d t}{\log t}
$$

for $x \geq 2$, which avoids the singularity at $x=1$. We have the relation

$$
\operatorname{Li}(x)=\operatorname{li}(x)-\operatorname{li}(2)
$$

Note: the Maxima documentation incorrectly states that

```
expintegral_li(x)
```

computes $\operatorname{Li}(x)$, but it actually ${ }^{2}$ computes $\operatorname{li}(x)$.
We also have the exponential integrals:
(1) There is the integral

$$
\operatorname{Ei}(x)=-\int_{-x}^{\infty} \frac{e^{-t}}{t} d t
$$

and the Maxima command is

```
expintegral_ei(x)
```

where the singularity at $t=0$ is handled via the Cauchy principal value (as in equation 12.5.2). This function is related to li( $x$ ) via

$$
\begin{equation*}
\operatorname{li}\left(e^{x}\right)=\operatorname{Ei}(x) \tag{12.5.3}
\end{equation*}
$$

and

[^37]

Figure 12.5.2. The Ei-function
plot2d (expintegral_ei(x),[x,-1,3])
produces figure 12.5.2. Note,

```
expintegral_li(x)
```

can produce incorrect results if $x$ is a complex number ${ }^{3}$. In this case, equation 12.5.3 on the previous page gives the correct value.
(2) The integral

$$
\mathrm{E}_{1}(x)=\int_{x}^{\infty} \frac{e^{-t}}{t} d t
$$

with a Maxima command

```
expintegral_e1(x)
```

that produces figure 12.5 .3 on the facing page.
(3) The sine integral

$$
\operatorname{Si}(x)=\int_{0}^{x} \frac{\sin t}{t} d t
$$

coded in Maxima as

## expintegral_si(x)

which is plotted in figure 12.5 .4 on the next page. It is well-known that

$$
\lim _{x \rightarrow \infty} \operatorname{Si}(x)=\frac{\pi}{2}
$$

[^38]

Figure 12.5.3. $\quad E_{1}$-function

Figure 12.5.4. The sine-integral

It turns out that the sine-integral is closely related to Gibbs phenomena, mentioned on page 58. The size of the jump (overshoot or undershoot) is approximately $9 \%$ and is exactly given by

$$
\frac{\mathrm{Si}(\pi)}{\pi}-\frac{1}{2}=0.08948987223608362 \ldots
$$

called the Wilbraham-Gibbs constant - see [20]. Incidentally, the phenomena was discovered by Wilbraham fifty years before Gibbs mentioned it, but it's named after Gibbs (as per mathematical tradition!).

Figure 12.5.5. The cosine-integral
(4) The cosine-integral

$$
\mathrm{Ci}(x)=-\int_{x}^{\infty} \frac{\cos t}{t} d t
$$

coded in Maxima as

```
expintegral_ci(x)
```

and plotted in figure 12.5.5.
(5) The hyperbolic sine integral:

$$
\operatorname{Shi}(x)=\int_{0}^{x} \frac{\sinh t}{t} d t
$$

coded in Maxima via

```
expintegral_shi (x)
```

(6) And the hyperbolic cosine integral:

$$
\operatorname{Chi}(x)=\gamma+\log x+\int_{0}^{x} \frac{\cosh t-1}{t} d t
$$

coded in Maxima via

```
expintegral_chi(x)
```

Here $\gamma$ is the Euler-Mascheroni constant, coded in Maxima as \%gamma.

## EXERCISES.

1. Write a function to compute $\operatorname{li}(x)$ from equation 12.5 . 2 on page 203 (i.e., without using Maxima's expintegral_li-function).
2. Find a relation between the functions $\mathrm{E}_{1}(x), \mathrm{Si}(x)$, and $\mathrm{Ci}(x)$.

### 12.6. Lambert functions

The Lambert- $W$ function is the inverse function to

$$
x e^{x}
$$

- which is sometimes called the product logarithm, because the conventional logarithm is the inverse function to $e^{x}$. Another name for it is the omega function. Like the logarithm, the $W$-function has many branches, denoted $W_{n}(z)$, and

$$
y=x e^{x}
$$

if and only if

$$
x=W_{n}(y)
$$

for some integer $n$. Unlike the logarithm, these branches are not equally spaced.

Two of them, $W_{0}(z)$ and $W_{-1}(z)$ (often written $W_{m}(z)$ ) are real-valued for real values of $z$ and the others are complex valued. If $z$ is real-valued, then $W_{0}(z)$ is well-defined for $0 \leq z$, and $W_{-1}(z)$ is defined for $-1 / e \leq z \leq$ 0 .

The command

## lambert_w (x)

computes $W_{0}(x)$ and the command

```
plot2d(lambert_w(x),[x,0,10]);
```

produces the plot in figure 12.6.1 on the following page.
The other branches, $W_{k}(z)$, of the Lambert function are given by the command
generalized_lambert_w ( k , z )
where

```
generalized_lambert_w(0, z)=lambert_w(z)
```

The command

```
plot2d(generalized_lambert_w(-1, z),[z,-1/%e,0])
```

produces the plot in figure 12.6 .2 on the next page.
The Lambert function has many applications in physics - see the paper [45].

Figure 12.6.1. The Lambert $W$ function

Figure 12.6.2. The Lambert function $W_{-1}(z)$

Johann Heinrich Lambert (1728-1777) was a polymath from the Republic of Mulhouse (today part of the province of Alsace, in France), who made important contributions to the subjects of mathematics, physics (particularly optics), philosophy, astronomy, and map projections.

The Lambert functions all satisfy the differential equation

$$
\frac{d W(z)}{d z}=\frac{W(z)}{z(1+W(z))}=\frac{1}{z+e^{W(z)}}
$$

which implies that it has applications to Michaelis-Menten kinetics involving the biochemistry of enzyme-catalysed reactions of one substrate and one product. it also has applications to ecology and evolution - see [27].

The Lambert function also has applications to the problem of the infinite power tower:

$$
y=x^{x^{x^{x}}}
$$

One might ask what this even means. Define a sequence

$$
\left\{t_{k}(x)\right\}
$$

by

$$
\begin{aligned}
t_{1}(x) & =x \\
t_{k+1}(x) & =x^{t_{k}(x)} \quad \text { for } k \text { an integer } \geq 1
\end{aligned}
$$

and

$$
\begin{equation*}
y=t_{\infty}(x)=\lim _{k \rightarrow \infty} t_{k}(x) \tag{12.6.1}
\end{equation*}
$$

if this limit exists.
Since the tower is infinite, we have

$$
t_{\infty+1}(x)=t_{\infty}(x)
$$

or

$$
\begin{equation*}
y=x^{y}=e^{y \log (x)} \tag{12.6.2}
\end{equation*}
$$

so that

$$
y e^{-y \log (x)}=1
$$

If we multiply by $-\log (x)$, we get

$$
-\log (x) y e^{-y \log (x)}=-\log (x)
$$

so

$$
-\log (x) y=W(-\log (x))
$$

and

$$
\begin{equation*}
y=-\frac{W(-\log (x))}{\log (x)}=t_{\infty}(x) \tag{12.6.3}
\end{equation*}
$$

Surprisingly, this limit exists for many values of $x$.
If we take the $1 / y$ power of equation 12.6.2, we get

$$
\begin{equation*}
y^{1 / y}=x \tag{12.6.4}
\end{equation*}
$$

which shows that equation 12.6 .3 actually solves for $y$ satisfying equation 12.6.4, given $x$.

## EXERCISES.

1. Compute $t_{\infty}(\sqrt{2})$ as in equations 12.6 .1 on the previous page and 12.6.3.
2. Estimate the largest finite value of $d$ such that $t_{\infty}(\sqrt{2}+d)$ is welldefined. Hint: start with $d=.01$. If the sequence $\left\{t_{k}(x)\right\}$ diverges, equation 12.6.3 on the preceding page will give complex numbers for $t_{\infty}(x)$. What is the limiting value (i.e., the largest finite value you can get) for $t_{\infty}(x)$ ?
3. If we define

we can compute
x : tow (3)
Why is this well-defined?

## CHAPTER 13

## The Zeta function

"God may not play dice with the universe, but something strange is going on with prime numbers. "

- taken from a talk given by Carl Pomerance on the Erdős-Kac theorem, San Diego in January 1997.

### 13.1. Properties of the $\zeta$-function

In this section, we will discuss Riemann's groundbreaking research (see [35] and the English translation, [49]) on Euler's Zeta function - a function so special it rates its own chapter. This involves the theory of functions of a complex variable, so the reader needs to be familiar with that - see [1].

Georg Friedrich Bernhard Riemann (1826-1866) was an influential German mathematician who made contributions to many fields including analysis, number theory and differential geometry. Riemann's work in differential geometry provided the mathematical foundation for Einstein's Theory of General Relativity (see [32]).

It all begins with Euler's zeta-function:

$$
\begin{equation*}
\zeta(s)=\sum_{n=1}^{\infty} \frac{1}{n^{s}} \tag{13.1.1}
\end{equation*}
$$

Maxima has a command to compute this

```
zeta(x)
```

and this gives exact values when they are known, so

```
zeta(2)
```

gives

$$
\frac{\pi^{2}}{6}
$$

Riemann first noted

$$
\int_{0}^{\infty} e^{-n x} x^{s-1} d x=\frac{\Gamma(s)}{n^{s}}
$$

which you can confirm using Maxima (and answering questions about $n$ and $s$ ). It follows that

$$
\int_{0}^{\infty}\left(e^{-x}+e^{-2 x}+e^{-3 x}+\cdots\right) x^{s-1} d x=\Gamma(s)\left(\frac{1}{1^{s}}+\frac{1}{2^{s}}+\frac{1}{3^{s}}+\cdots\right)
$$

Figure 13.1.1. The contour, $C$

The infinite series

$$
e^{-x}+e^{-2 x}+e^{-3 x}+\cdots=e^{-x}+\left(e^{-x}\right)^{2}+\left(e^{-x}\right)^{3}+\cdots
$$

is the geometric series equal to

$$
e^{-x} \frac{1}{1-e^{-x}}=\frac{e^{x}}{e^{x}} \frac{e^{-x}}{1-e^{-x}}=\frac{1}{e^{x}-1}
$$

or (what amounts to the same thing)

$$
\frac{1}{1-e^{-x}}-1
$$

so we get

$$
\Gamma(s) \zeta(s)=\int_{0}^{\infty} \frac{x^{s-1}}{e^{x}-1} d x
$$

It's interesting that the mere subtraction of 1 in the denominator transforms this integral from $\Gamma(s)$ to $\Gamma(s) \zeta(s)$.

Next, Riemann extends the definition of $\zeta(s)$ to the whole complex plane by evaluating the integral

$$
\int_{C} \frac{(-z)^{s-1}}{e^{z}-1} d z
$$

where $C$ is the contour in figure 13.1.1, and the branch of $\log (-z)$ used in calculating $(-z)^{s-1}$ is the one where the logarithm is real for negative values of $z$.

We will ultimately take the limit as $\epsilon \rightarrow 0$ and the circle around the origin has a radius that goes to 0 as well. We split the contour, $C$, into three parts. Note that $-z=e^{ \pm \pi i} \cdot z$ and our three parts are
(1) $\gamma_{1}$, the path above the real axis from $\infty$ to $\epsilon$. Since the argument of $z$ goes from $-\pi$ to $+\pi$, we will start with $-z=e^{-\pi i} z$

$$
\begin{aligned}
\int_{\gamma_{1}} \frac{(-z)^{s-1}}{e^{z}-1} d z & =\int_{\infty}^{\epsilon} e^{-(s-1) \pi i} \frac{z^{s-1}}{e^{z}-1} d z \\
& =e^{-s \pi i} e^{\pi i} \int_{\infty}^{\epsilon} \frac{z^{s-1}}{e^{z}-1} d z \\
& =e^{-s \pi i} \int_{\epsilon}^{\infty} \frac{z^{s-1}}{e^{z}-1} d z
\end{aligned}
$$

(2) $\gamma_{2}$, the small circle around the origin. In this case

$$
\frac{1}{e^{z}-1} \sim \frac{1}{z}
$$

as the circle shrinks to the origin, so

$$
\frac{z^{s-1}}{e^{z}-1} \sim z^{s-2}
$$

which has a residue of 0 unless $s=1$ - but we already know $\zeta(s)$ has a singularity at $s=1$.
(3) $\gamma_{3}$, the path below the real axis from $\epsilon$ to $\infty$. Here $-z=e^{+\pi i} z$ (since we have wrapped around the origin in a positive direction) so

$$
\begin{aligned}
\int_{\gamma_{3}} \frac{(-z)^{s-1}}{e^{z}-1} d z & =\int_{\epsilon}^{\infty} e^{+(s-1) \pi i} \frac{z^{s-1}}{e^{z}-1} d z \\
& =e^{s \pi i} e^{-\pi i} \int_{\epsilon}^{\infty} \frac{z^{s-1}}{e^{z}-1} d z \\
& =-e^{s \pi i} \int_{\epsilon}^{\infty} \frac{z^{s-1}}{e^{z}-1} d z
\end{aligned}
$$

We conclude (as Riemann did) that

$$
\left(e^{-\pi i s}-e^{\pi i s}\right) \Gamma(s) \zeta(s)=\int_{C} \frac{(-z)^{s-1}}{e^{z}-1} d z
$$

or

$$
\begin{equation*}
2 \sin (\pi s) \Gamma(s) \zeta(s)=i \int_{C} \frac{(-z)^{s-1}}{e^{z}-1} d z \tag{13.1.2}
\end{equation*}
$$

for $s \neq 1$. Note that $\sin (\pi s) \Gamma(s)$ is finite for $s<0$. Even though $\Gamma(s)$ has singularities at all negative integers, $\sin (\pi s)$ vanishes for all integers, so it "cancels out" these singularities. The Euler reflection formula 12.1.3 on page 190 shows that

$$
2 \sin (\pi s) \Gamma(s)=\frac{2 \pi}{\Gamma(1-s)}
$$

which implies that it's also nonzero for $s<0$.
If we traverse the contour, $C$, in a negative direction, this inverts the sign of the result. If we do this and invert the interior of this contour (i.e., regard it as enclosing the exterior of the narrow strip around the positive real-axis) the integral is inverted again - i.e., its original value is restored.

We get a formula

$$
2 \sin (\pi s) \Gamma(s) \zeta(s)=i \int_{\overline{-C}} \frac{(-z)^{s-1}}{e^{z}-1} d z
$$

where $-C$ is the contour $C$ traversed in the opposite direction and $\overline{-C}$ represents the result of regarding it as enclosing the entire complex plane outside the narrow strip around the positive real-axis.

Evaluating this integral is straightforward, using the calculus of residues. Nonzero residues occur when $s=2 n \pi i$ where $n$ is a nonzero integer, and they are equal to $(-2 n \pi i)^{s-1} \cdot(-2 \pi i)$.

We get the formula, well-defined for $s<0$ :

$$
2 \sin (\pi s) \Gamma(s) \zeta(s)=(2 \pi)^{s} \sum_{n=1}^{\infty} n^{s-1}\left(i^{s-1}+(-i)^{s-1}\right)
$$

which is a kind of complement to equation 13.1.1 on page 211. It immediately implies that $\zeta(-2 n)=0$ for $n$ a positive integer. At this point, Riemann observed that the Euler reflection formula for the gamma function (equation 12.1.3 on page 190) implies one for the zeta function:

$$
\begin{equation*}
\Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}} \zeta(s)=\Gamma\left(\frac{1-s}{2}\right) \pi^{-\frac{1-s}{2}} \zeta(1-s) \tag{13.1.3}
\end{equation*}
$$

which we can call the Riemann reflection formula. Note that when $s=1 / 2$, both sides of this equation become identical. This suggested to Riemann that the line $\Re(s)=1 / 2$ is critical.

Starting with ${ }^{1}$

$$
\int_{0}^{\infty} e^{-n^{2} \pi x} x^{\frac{s}{2}-1} d x=\frac{1}{n^{s}} \Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}}
$$

so that

$$
\begin{equation*}
\Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}} \zeta(s)=\int_{0}^{\infty} \psi(x) x^{\frac{s}{2}-1} d x \tag{13.1.4}
\end{equation*}
$$

where

$$
\psi(x)=\sum_{n=1}^{\infty} e^{-n^{2} \pi x}
$$

for $x>0$.
Riemann then cited the remarkable result

$$
\begin{equation*}
2 \psi(x)+1=x^{-1 / 2}\left(2 \psi\left(\frac{1}{x}\right)+1\right) \tag{13.1.5}
\end{equation*}
$$

and gave a reference to a paper of Jacobi which doesn't contain this formula. It appears at the bottom of page 307 in another paper of Jacobi (see [23]) which attributes the result to unpublished work of Poisson. See appendix $C$ on page 233 for a detailed proof.

We rewrite the integral in equation 13.1.4 as

$$
\begin{equation*}
\Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}} \zeta(s)=\int_{1}^{\infty} \psi(x) x^{\frac{s}{2}-1} d x+\int_{0}^{1} \psi(x) x^{\frac{s}{2}-1} d x \tag{13.1.6}
\end{equation*}
$$

[^39]and we rewrite equation 13.1 .5 on the preceding page as
\[

$$
\begin{equation*}
\psi(x)=x^{-1 / 2}\left(\psi\left(\frac{1}{x}\right)+\frac{1}{2}\right)-\frac{1}{2} \tag{13.1.7}
\end{equation*}
$$

\]

and use it to reformulate the term from 0 to 1 in equation 13.1.6 on the facing page as

$$
\begin{aligned}
\int_{0}^{1} \psi(x) x^{\frac{s}{2}-1} d x= & \int_{0}^{1}\left(x^{-1 / 2}\left(\psi\left(\frac{1}{x}\right)+\frac{1}{2}\right)-\frac{1}{2}\right) x^{\frac{s}{2}-1} d x \\
= & \int_{0}^{1} x^{-1 / 2} x^{\frac{s}{2}-1} \psi\left(\frac{1}{x}\right) d x \\
& +\int_{0}^{1} x^{\frac{s}{2}-1}\left(\frac{x^{-1 / 2}}{2}\right) d x-\int_{0}^{1} x^{\frac{s}{2}-1} \frac{1}{2} d x
\end{aligned}
$$

so we get

$$
\begin{gathered}
\Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}} \zeta(s)=\int_{1}^{\infty} \psi(x) x^{\frac{s}{2}-1} d x+\int_{0}^{1} \psi\left(\frac{1}{x}\right) x^{\frac{s-3}{2}} d x \\
+\frac{1}{2} \int_{0}^{1}\left(x^{\frac{s-3}{2}}-x^{\frac{s}{2}-1}\right) d x
\end{gathered}
$$

Now we do a $u$-substitution on the second of these three terms on the right

$$
u=\frac{1}{x}
$$

so

$$
\begin{aligned}
d x & =-\frac{1}{u^{2}} d u \\
\int_{0}^{1} \psi\left(\frac{1}{x}\right) x^{\frac{s-3}{2}} d x & =-\int_{\infty}^{1} \psi(u) u^{-\left(\frac{s-3}{2}\right)} u^{-2} d u \\
& =\int_{1}^{\infty} \psi(u) u^{\frac{3-s}{2}-2} d u \\
& =\int_{1}^{\infty} \psi(u) u^{-\frac{1+s}{2}} d u
\end{aligned}
$$

and we finally get (replacing $u$ in the integral above by $x$ )

$$
\Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}} \zeta(s)=\frac{1}{s(s-1)}+\int_{1}^{\infty} \psi(x)\left(x^{\frac{s}{2}-1}+x^{-\frac{1+s}{2}}\right) d x
$$

Now, Riemann sets $s=\frac{1}{2}+t i$ and

$$
\begin{equation*}
\Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}} \zeta(s)(s-1)=\xi(t) \tag{13.1.8}
\end{equation*}
$$

so that the line $\Re(s)=\frac{1}{2} \subset \mathbb{C}$ gets transformed to the real axis and Maxima easily computes this last transformation.

$$
\mathrm{z}: \mathrm{x}^{\wedge}(\mathrm{s} / 2-1)+\mathrm{x}^{\wedge}(-(1+\mathrm{s}) / 2)
$$

and

```
subst(1/2+t*%i,s,z ;
```

gives

$$
x^{\frac{\% i \cdot t+\frac{1}{2}}{2}-1}+x^{\frac{-\% i \cdot t-\frac{3}{2}}{2}}
$$

Now, we type
assume ( $x>0$ );
and
rectform (z);
gives

$$
\frac{2 \cos \left(\frac{t \log (x)}{2}\right)}{x^{\frac{3}{4}}}
$$

We ultimately get

$$
\begin{equation*}
\xi(t)=\frac{1}{2}-\left(t^{2}+\frac{1}{4}\right) \int_{1}^{\infty} \psi(x) x^{-\frac{3}{4}} \cos \left(\frac{t}{2} \log (x)\right) d x \tag{13.1.9}
\end{equation*}
$$

Now we type
integrate $\left(\left(t^{\wedge} 2+1 / 4\right) * x^{\wedge}(-3 / 4) * \cos ((t / 2) * \log (x)), x\right)$;
to get

$$
\frac{4\left(t^{2}+\frac{1}{4}\right) x^{\frac{1}{4}}\left(2 t \sin \left(\frac{t \log (x)}{2}\right)+\cos \left(\frac{t \log (x)}{2}\right)\right)}{4 t^{2}+1}
$$

and

## ratsimp(\%)

gives

$$
x^{\frac{1}{4}}\left(2 t \sin \left(\frac{t \log (x)}{2}\right)+\cos \left(\frac{t \log (x)}{2}\right)\right)
$$

which means we can integrate the right side of equation 13.1.9 by parts to get

$$
\begin{aligned}
\xi(t) & =\frac{1}{2}+\int_{1}^{\infty} \psi^{\prime}(x) x^{\frac{1}{4}}\left(2 t \sin \left(\frac{t \log (x)}{2}\right)+\cos \left(\frac{t \log (x)}{2}\right)\right) d x \\
& +\psi(1)
\end{aligned}
$$

Now we write $x^{1 / 4}=x^{3 / 2} \cdot x^{-5 / 4}$ and integrate by parts a second time.
integrate $\left(x^{\wedge}(-5 / 4) *(2 * t * \sin ((t * \log (x)) / 2)\right.$ $+\cos ((t * \log (x)) / 2)), x)$;
gives

$$
4\left(\frac{2 t \sin \left(\frac{t \log (x)}{2}\right)-\cos \left(\frac{t \log (x)}{2}\right)}{\left(4 t^{2}+1\right) x^{\frac{1}{4}}}+\frac{2 t\left(-\sin \left(\frac{t \log (x)}{2}\right)-2 t \cos \left(\frac{t \log (x)}{2}\right)\right)}{\left(4 t^{2}+1\right) x^{\frac{1}{4}}}\right)
$$

and

```
expand(%)
```

gives

$$
-\frac{16 t^{2} \cos \left(\frac{t \log (x)}{2}\right)}{4 t^{2} x^{\frac{1}{4}}+x^{\frac{1}{4}}}-\frac{4 \cos \left(\frac{t \log (x)}{2}\right)}{4 t^{2} x^{\frac{1}{4}}+x^{\frac{1}{4}}}
$$

A final

```
ratsimp(%)
```

gives

$$
-\frac{4 \cos \left(\frac{t \log (x)}{2}\right)}{x^{\frac{1}{4}}}
$$

So our second integration by parts gives

$$
\xi(t)=\frac{1}{2}+\psi(1)+\psi^{\prime}(1)+4 \int_{1}^{\infty} \frac{d}{d x}\left(x^{\frac{3}{2}} \psi^{\prime}(x)\right) x^{-\frac{1}{4}} \cos (t \log (x) / 2) d x
$$

Differentiating equation 13.1 .7 on page 215 by $x$ (and plugging in $x=1$ ) gives

$$
\frac{1}{2}+\psi(1)+\psi^{\prime}(1)=0
$$

so

$$
\begin{equation*}
\xi(t)=4 \int_{1}^{\infty} \frac{d}{d x}\left(x^{\frac{3}{2}} \psi^{\prime}(x)\right) x^{-\frac{1}{4}} \cos (t \log (x) / 2) d x \tag{13.1.10}
\end{equation*}
$$

It's interesting that, in his paper [35], Riemann goes from equation 13.1.9 on the preceding page to equation 13.1.10 in a single step ${ }^{2}$.

This is an entire function of $t$ (i.e., no singularities) and Riemann conjectured that all of its zeroes lie on the real line. This is equivalent to saying all of the zeroes of $\zeta(z)$ that aren't of the form $-2 n$ for $n \in \mathbb{Z}^{+}$lie on the line $\Re(z)=\frac{1}{2}$ - which is the famous Riemann hypothesis. No one has found a counterexample to it or succeeded in proving it. Experiments have verified it up to $t<12,363,153,437,138$.

Since this is an entire function, Riemann conjectured that it can be written as an "infinite polynomial"

$$
\begin{equation*}
\xi(t)=\xi(0) \prod_{i=1}^{\infty}\left(1-\frac{t}{\rho_{i}}\right) \tag{13.1.11}
\end{equation*}
$$

where the $\rho_{i}$ run over all the zeroes of $\xi(t)$. Although this formula wasn't rigorous at the time, Weierstrass later proved that such infinite polynomials could exist and equal entire functions - under the right conditions. Later, Hadamard proved that the right conditions exist in this case, so Riemann's formula is correct.

Since $\xi(t)$ is actually a function of $t^{2}$, every zero, $\rho$, has a complementary one, $-\rho$, we usually write formula 13.1.11 as

$$
\begin{equation*}
\xi(t)=\xi(0) \prod_{i=1}^{\infty}\left(1-\frac{t}{\rho_{i}}\right)\left(1-\frac{t}{-\rho_{i}}\right)=\xi(0) \prod_{i=1}^{\infty}\left(1-\frac{t^{2}}{\rho_{i}^{2}}\right) \tag{13.1.12}
\end{equation*}
$$

[^40]
### 13.2. A "formula" for prime numbers

Recall Euler's original formula for the Zeta function, equation 13.1.1 on page 211 for $x>1$, which he immediately rewrote as

$$
\begin{equation*}
\zeta(x)=\prod_{p \text { prime }} \frac{1}{1-p^{-x}} \tag{13.2.1}
\end{equation*}
$$

The way to see this is to recall the infinite series

$$
\begin{aligned}
\frac{1}{1-p^{-x}} & =1+p^{-x}+p^{-2 x}+\cdots \\
& =1+p^{-x}+\left(p^{2}\right)^{-x} \cdots
\end{aligned}
$$

The product

$$
\prod_{p \text { prime }}\left(1+p^{-x}+\left(p^{2}\right)^{-x} \cdots\right)
$$

will be a sum of terms of the form

$$
\frac{1}{\left(p_{1}^{n_{1}} \cdots p_{k}^{n_{k}}\right)^{x}}
$$

with all possible primes raised to all possible powers, i.e. the series in equation 13.1.1 on page 211.

If we take the logarithm of equation 13.2.1, we get

$$
\log \zeta(x)=-\sum_{p \text { prime }} \log \left(1-p^{-x}\right)
$$

and plug in the Taylor series ${ }^{3}$ for $\log \left(1-p^{-x}\right)$ to get

$$
\log \zeta(x)=\sum_{p \text { prime }} p^{-x}+\frac{p^{-2 x}}{2}+\frac{p^{-3 x}}{3} \cdots
$$

Now we define a function that counts primes
(13.2.2) $\quad \pi(x)= \begin{cases}\text { number of primes }<x & \text { if } x \text { is not a prime } \\ 1 / 2+\text { number of primes }<x & \text { if } x \text { is a prime }\end{cases}$

This is a discontinuous function whose value at each jump-point is the mean of the value before the jump and the one after.

Now define

$$
\begin{equation*}
R(x)=\pi(x)+\frac{\pi\left(x^{1 / 2}\right)}{2}+\frac{\pi\left(x^{1 / 3}\right)}{3}+\cdots \tag{13.2.3}
\end{equation*}
$$

Note that

$$
\begin{aligned}
p^{-x} & =x \int_{p}^{\infty} s^{-x-1} d s \\
p^{-2 x} & =x \int_{p^{2}}^{\infty} s^{-x-1} d s
\end{aligned}
$$

etc.

[^41]so we conclude that
$$
\frac{\log \zeta(x)}{x}=\int_{1}^{\infty} R(s) s^{-x-1} d s
$$

After several steps using Fourier transforms, Riemann got

$$
R(x)=\frac{1}{2 \pi i} \int_{a-i \infty}^{a+i \infty} \frac{\log \zeta(s)}{s} x^{s} d s
$$

Now we use formulas from the preceding section to estimate $\log \zeta(s) / s$, namely equations 13.1.8 on page 215 and 13.1.12 on page 217.

$$
\begin{equation*}
\log \zeta(s)=\log \xi(s)-\log \Gamma\left(\frac{s}{2}\right)+\frac{s}{2} \log (\pi)-\log (s-1) \tag{13.2.4}
\end{equation*}
$$

If we try to integrate this in a straightforward fashion, several terms in the integral diverge (particularly the term $\frac{s}{2} \log (\pi)$ ). We choose to integrate by parts: assuming that $x^{5}$ was a derivative of something with respect to $s$. Note that

```
integrate( }\mp@subsup{\textrm{x}}{}{\wedge}\textrm{s},\textrm{s}\mathrm{ );
```

produces

$$
\frac{x^{s}}{\log (x)}
$$

Since

$$
\lim _{T \rightarrow \pm \infty} \frac{\log \zeta(a+i T)}{(a+i T)} x^{a+i T}=0
$$

since $x^{a+i T}$ oscillates as $T \rightarrow \infty$ and $\log \zeta(a+i T)$ remains bounded, so the denominator kills off the fraction.

It follows that integrating by parts gives

$$
\begin{equation*}
R(x)=-\frac{1}{2 \pi i \log x} \int_{a-i \infty}^{a+i \infty} \frac{d}{d s}\left(\frac{\log \zeta(s)}{s}\right) x^{s} d s \tag{13.2.5}
\end{equation*}
$$

We will start by computing

$$
-\frac{1}{2 \pi i \log x} \int_{a-i \infty}^{a+i \infty} \frac{d}{d s}\left(\frac{\log (s-1)}{s}\right) x^{s} d s
$$

since it is probably the largest term. We compute

$$
G(\beta)=-\frac{1}{2 \pi i \log x} \int_{a-i \infty}^{a+i \infty} \frac{d}{d s}\left(\frac{\log (s / \beta-1)}{s}\right) x^{s} d s
$$

and consider the limit as $\beta \rightarrow 1$. This integral is well-defined if $a>\Re(\beta)$ because

$$
\begin{aligned}
\left|\frac{d}{d s}\left(\frac{\log (s / \beta-1)}{s}\right)\right| & =\left|\frac{1}{s(s-\beta)}-\frac{\log (s-\beta)}{s^{2}}\right| \\
& \leq \frac{1}{|s(s-\beta)|}+\frac{|\log (s-\beta)|}{|s|^{2}}
\end{aligned}
$$

which are integrable. We can differentiate $G(\beta)$ with respect to $\beta$ :

$$
G^{\prime}(\beta)=\frac{1}{2 \pi i \log x} \int_{a-i \infty}^{a+i \infty} \frac{d}{d s}\left(\frac{1}{\beta(s-\beta)}\right) x^{s} d s
$$

Now integration by parts gives

$$
G^{\prime}(\beta)=-\frac{1}{2 \pi i} \int_{a-i \infty}^{a+i \infty} \frac{1}{\beta(s-\beta)} x^{s} d s
$$

This resists brute-force efforts to integrate it (i.e., plug in $s=a+i T$, and integrate with $T$ running from $-\infty$ to $\infty$ ). We use a bit of finesse: Regard the path from $a-i \infty$ to $a+i \infty$ as a circle on the Riemann sphere. It encloses the part of $\mathbb{C}$ to the left of it, i.e. the half plane $\Re(z)<a$. The integral is determined by its residue at the singularity $s=\beta$ (see [1] for information on the Residue Theorem). We get

$$
G^{\prime}(\beta)= \begin{cases}\frac{x^{\beta}}{\beta}=\int_{0}^{x} u^{\beta-1} d u & \text { if } a>\Re(\beta) \\ 0 & \text { if } a<\Re(\beta)\end{cases}
$$

So

$$
\begin{aligned}
G(\beta) & =\int\left\{\int_{0}^{x} u^{\beta-1} d u\right\} d \beta \\
& =\int_{0}^{x}\left\{\int u^{\beta-1} d \beta\right\} d u \\
& =\int_{0}^{x}\left\{\frac{u^{\beta-1}}{\log u}\right\} d u \quad \text { now set } v=u^{\beta} \\
& =\frac{1}{\beta} \int_{0}^{x^{\beta}} \frac{d v}{\log v^{1 / \beta}} \\
& =\int_{0}^{x^{\beta}} \frac{d v}{\log v}
\end{aligned}
$$

We get ${ }^{4}$

$$
F(x)=\operatorname{li}\left(x^{\beta}\right)+\operatorname{constant}(x)
$$

Riemann then argues that this constant is identically 0 . If $\beta=1$, we get the statement of the Prime Number Theorem

$$
\pi(x) \sim \operatorname{li}(x)
$$

Now we can introduce the remaining terms of equation 13.2.4 on the previous page into equation 13.2.5 to get

$$
\begin{aligned}
& R(x)=\operatorname{li}(x)-\sum_{\xi(\rho)=0}\left(\operatorname{li}\left(x^{\frac{1}{2}+i \rho}\right)+\operatorname{li}\left(x^{\frac{1}{2}-i \rho}\right)\right) \\
&+\int_{x}^{\infty} \frac{d u}{\left(u^{2}-1\right) u \log u}+\log \xi(0)
\end{aligned}
$$

We can plot this function, using table on the facing page of the first few values of $\rho$. The following function uses this table:

[^42]| 14.134725 |
| :--- |
| 21.022039 |
| 25.010857 |
| 30.424876 |
| 32.935061 |
| 37.586178 |
| 40.918719 |
| 43.327073 |
| 48.005150 |
| 49.773832 |
| First few zeros of $\xi(t)$ |

```
zeros: matrix(
[14.1347250,21.022039,25.010857,30.424876,
32.935061,37.586178,40.918719,43.327073,
48.005150,49.773832]
);
R(x):= block ([accum:expintegral_li(x)],
    for i :1 step 1 thru 10 do (
        accum:accum-
            expand(float(expintegral_ei(
            log(x)*(1/2+%i*zeros[1,i])))
            +float(expintegral_ei(
            log(x)*(1/2-%i * zeros[1,i]))))
            ),
        realpart(accum)
    )
```

The command

```
plot2d(R(x),[x,2,100])
```

produces the plot in figure on the next page. It is well-known that there are 25 primes $<100$, so the plot is fairly accurate ${ }^{5}$.

The reader will doubtless have several questions:
(1) why do we have expintegral_ei? This is because expintegral_li produces incorrect results for complex arguments, so we use equation 12.5.3 on page 203. It's also more efficient to compute

$$
\log (x) \cdot\left(1 / 2+i \cdot \operatorname{zeros}_{1, i}\right)
$$

than

$$
\log \left(x^{1 / 2+i \cdot \text { zeros }_{1, i}}\right)
$$

[^43]

Figure 13.2.1. Plot of $R(x)$
(2) Why do we have expand and float? This is because Maxima wants to do exact symbolic computations. We have to force it to do numeric computations.
(3) $R(x)$, as defined above counts primes and powers of primes. How do we get a formula that only counts primes ${ }^{6}$ ? This is answered below.
Recall equations 13.2.2 on page 218 and 13.2.3 on page 218. The Möbius Inversion Theorem (see [25]) states that we can invert equation 13.2.3 on page 218 to get

$$
\begin{equation*}
\pi(x)=\sum_{k=1}^{\infty} \mu(k) \frac{R\left(x^{1 / k}\right)}{k} \tag{13.2.6}
\end{equation*}
$$

where $\mu(k)$ is the Möbius function, defined by

$$
\mu(k)= \begin{cases}0 & \text { if } k \text { is divisible by the square of any prime } \\ (-1)^{\ell} & \text { if } k=p_{1} \cdots p_{\ell} \text { where they are all distinct primes }\end{cases}
$$

Maxima implements the Möbius function via the command

## moebius (x)

August Ferdinand Möbius (1790-1868) was a German mathematician and astronomer popularly known for his discovery of the Möbius strip (although he made many other contributions to mathematics, including Möbius transformations, the Möbius function in combinatorics and the Möbius inversion formula).

In our case we can define

[^44]

Figure 13.2.2. Approximate $\pi(x)$

$$
\begin{aligned}
\operatorname{pi}(x): & =R(x)-R\left(x^{\wedge}(1 / 2)\right) / 2-R\left(x^{\wedge}(1 / 3)\right) / 3 \\
& -R\left(x^{\wedge}(1 / 5)\right) / 5+R\left(x^{\wedge}(1 / 6)\right) / 6
\end{aligned}
$$

and (see section F. 5 on page 262) the command

```
draw(
    gr2d(line_width=2,color=black,
        explicit(
            pi(x),
            x,2,20
                ),line_type=dots,
        parametric (3,t,t,0,8),
        parametric (5,t,t,0,8),
        parametric (7,t,t,0,8),
        parametric(11,t,t,0,8),
        parametric(13,t,t,0,8),
        parametric (17,t,t,0,8),
        parametric(19,t,t,0,8)
        )
        );
```

produces figure 13.2.2, which jumps every time it passes a prime.
We can also plot this to 100 to get figure 13.2.3 on the following page, which correctly estimates the number of primes $<100$ as 25 .

Figure 13.2.3. First 100 primes (approximately)

## EXERCISES.

1. For a given value of $x$, show that equation 13.2 .3 on page 218 and equation 13.2.6 on page 222 are finite sums.
2. Verify the The Möbius Inversion Theorem by plugging equation 13.2.3 on page 218 into equation 13.2.6 on page 222.

## APPENDIX C

## Functional equation

## C.1. Poisson summation

In this section, we will prove the functional equation of the $\psi$-function used in section 13 on page 211.

Baron Siméon Denis Poisson FRS FRSE (1781-1840) was a French mathematician and physicist who worked on statistics, complex analysis, partial differential equations, the calculus of variations, analytical mechanics, electricity and magnetism, thermodynamics, elasticity, and fluid mechanics.

THEOREM C.1.1 (Poisson Summation formula). If $f(x)$ is a smooth function such that

$$
\int_{-\infty}^{\infty}|f(x)| d x
$$

is well-defined and finite and

$$
\hat{f}(u)=\int_{-\infty}^{\infty} f(x) e^{-2 \pi i x u} d x
$$

is its Fourier transform, then

$$
\begin{equation*}
\sum_{n>-\infty}^{\infty} f(n)=\sum_{k>-\infty}^{\infty} \hat{f}(k) \tag{С.1.1}
\end{equation*}
$$

Proof. Create a periodic function with period 1:

$$
F(x)=\sum_{n>-\infty}^{\infty} f(x+n)
$$

and expand it into a Fourier series

$$
\begin{equation*}
F(x)=\sum_{n>-\infty}^{\infty} a_{n} e^{2 \pi i n x} \tag{C.1.2}
\end{equation*}
$$

where the Fourier coefficients are given by

$$
\begin{aligned}
a_{n}= & \int_{-\infty}^{\infty} F(x) e^{-2 \pi i n x} d x \\
= & \sum_{m>-\infty}^{\infty} \int_{0}^{1} f(x+m) e^{-2 \pi i n x} d x \\
= & \sum_{m>-\infty}^{\infty} \int_{m}^{m+1} f(y) e^{-2 \pi i n(y-m)} d y \\
& \sum_{m>-\infty}^{\infty} e^{2 \pi i n m} \int_{m}^{m+1} f(y) e^{-2 \pi i n y} d y \\
= & \int_{-\infty}^{\infty} f(x) e^{-2 \pi i n y} d y=\hat{f}(-n)
\end{aligned}
$$

since $e^{2 \pi i n m}=1$.
If we set $x=0$ in equation C.1.2 on the preceding page, we get equation C.1.1 on the previous page.

## C.2. The main result

Suppose

$$
G(x)=\sum_{n>-\infty}^{\infty} e^{-\pi n^{2} x}=1+2 \psi(x)
$$

We can regard this as the sum of values of a function

$$
f(u)=e^{-\pi u^{2} x}
$$

and take its Fourier transform. Here, $u$ is the independent variable, $x$ is a parameter, and $y$ is the new variable (introduced by the Fourier transform). Typing
integrate $\left(\% e^{\wedge}\left(-\% \mathrm{pi} * \mathrm{u}^{\wedge} 2 * \mathrm{x}\right) * \% \mathrm{e}^{\wedge}(2 * \% \mathrm{pi} * \% \mathrm{i} * \mathrm{u} * \mathrm{y})\right.$, u, minf, inf$)$
gives

$$
\frac{e^{-\frac{\pi \cdot y^{2}}{x}}}{\sqrt{x}}
$$

so

$$
\sum_{n>-\infty}^{\infty} e^{-\pi n^{2} x}=\frac{1}{\sqrt{x}} \sum_{n>-\infty}^{\infty} e^{-\pi n^{2} / x}
$$

and

$$
\begin{equation*}
G(x)=\frac{1}{\sqrt{x}} G\left(\frac{1}{x}\right) \tag{С.2.1}
\end{equation*}
$$

## APPENDIX D

## Fermat factorization

## D.1. The algorithm

Suppose $N$ is an odd integer greater than 1 and $N=u \cdot v$ where $u$ and $v$ are (odd) integers. Fermat factorization is based on the equation

$$
N=\left(\frac{u+v}{2}\right)^{2}-\left(\frac{u-v}{2}\right)^{2}
$$

or

$$
\left(\frac{u+v}{2}\right)^{2}-N=\left(\frac{u-v}{2}\right)^{2}
$$

Since $u$ and $v$ are both odd, their sum and differences are even, so dividing by 2 gives us integers.

Oddly enough, this gives us a way to find $u$ or $v$ if the difference between them isn't too great.

We compute

$$
k^{2}-N
$$

for $k=\lceil\sqrt{N}\rceil,\lceil\sqrt{N}\rceil+1,\lceil\sqrt{N}\rceil+2, \ldots$ and test whether the difference is a perfect square. If it is, say $m^{2}$, then $u=k \pm m$ and we have found a factor of $N$.

Here $\lceil x\rceil$ is the ceiling function, the least integer that is $\geq x$. In Maxima, it is coded via

```
ceiling(x)
```

It is a complement to the floor-command

```
floor(x)
```

which returns the greatest integer $\leq x$.
In this example, we will use the isqrt-command which computes integer square roots of very large numbers - i.e., isqrt(n) computes the largest integer, $k$, such that $k^{2} \leq n$.

EXAMPLE D.1.1. Let $u=1000003$ and $v$ be the next prime, which is 1000033. We compute

$$
u \cdot v=1000008000015
$$

and

```
ceiling(float(sqrt(1000008000015)))
```

is

1000018
and
$1000018 \wedge 2-n$;
gives

$$
225=15^{2}
$$

so we immediately get both factors of $n$ : $1000018-15=1000003$ and $1000018+15=1000033$.

The "lucky accident" in this example (where the answer occurs on the first iteration) turns out to always occur if $\frac{1}{2 q}\left(\frac{p-q}{2}\right)^{2}<1$, where $p$ is the larger of the two primes - see section D. 2 on the facing page below.

We can write a Maxima program implementing this algorithm. First, we need a function to determine whether a number is a perfect square:

```
square_p(n):= block(
    [sqval:isqrt(n)],
    /* test whether the square root
        is an integer */
    is (n=sqval^2)
);
```

Now for the main function:

```
one_factor (n):= block(
    [start:isqrt(n),test,val],
    for x:0 step 1 thru 100 do
    (
    /* Note: for-loops cannot handle very large numbers
        so we only iterate through the increments to
        ceiling(sqrt(n))*/
        val:x+start,
        test:val^2-n,
        if(square_p(test)) then
            return(val-isqrt(test))
/* If test is a perfect square, then
        isqrt is equal to its square root */
    )
);
```

For instance

```
one_factor(2251644881930449333);
```

returns
1500450271
after 3 iterations of the loop.
If

$$
\begin{gathered}
n=8956494142912946049415883818712449246261041215620 \\
42227318384494381723497514540860474803494041479529
\end{gathered}
$$

p:one_factor $(n)$ instantly comes back with
29927402397991286489627837734179186385188296382227
a prime factor of $n$, and $n / p$ produces
29927402397991286489627904551843385490310576382227
the other prime factor.

## D.2. Derivation of the upper bound for the number of iterations

Suppose $0<q<p$ and $N=p q$. We have

$$
N=\left(\frac{p+q}{2}\right)^{2}-\left(\frac{p-q}{2}\right)^{2}
$$

or

$$
\begin{aligned}
\left(\frac{p+q}{2}\right)^{2}-N & =\left(\frac{p-q}{2}\right)^{2} \\
\left(\frac{p+q}{2}-\sqrt{N}\right)\left(\frac{p+q}{2}+\sqrt{N}\right) & =\left(\frac{p-q}{2}\right)^{2}
\end{aligned}
$$

Note that

$$
\left(\frac{p+q}{2}+\sqrt{N}\right)>2 q
$$

so dividing by $2 q$ will give a larger result than dividing by $\left(\frac{p+q}{2}+\sqrt{N}\right)$ (to get $\left(\frac{p-q}{2}\right)^{2}$ ). We get

$$
0<\frac{p+q}{2}-\sqrt{N}<\frac{1}{2 q}\left(\frac{p-q}{2}\right)^{2}
$$

and the quantity on the right is an approximate upper bound to the number of iterations required.

EXERCISES.

1. Factor 15241580725499173.

## APPENDIX E

## The Maxima Programming language

## E.1. Introduction

Maxima implements a powerful programming language that is used for the functions in its libraries. We have already seen how to program a function and the block-construct. This is not an exhaustive treatment of the language by any means; it should be enough to understand the programs in the book.

## E.2. Commands for functions and equations

Recall that we code functions via
f(args):=code;
and a memoized function (usually, of a single argument although multiple integer arguments are possible) via
flarg]:=code;

We can access the arguments of a function-call via the args command:

$$
\begin{gathered}
\operatorname{args}(\mathrm{f}(\mathrm{a}, \mathrm{~b}, \mathrm{c})) \\
{[\mathrm{a}, \mathrm{~b}, \mathrm{c}]}
\end{gathered}
$$

and the function-name via the op-command:

$$
\underset{f}{\mathbf{o p}(\mathrm{f}(\mathrm{a}, \mathrm{~b}, \mathrm{c}))}
$$

Given an equation, $a=b$, we can isolate the sides of the equation via the rhs and lhs commands:

```
rhs(a=b)
    b
    lhs(a=b)
    a
```

We have the subst-command or. The command's format is

```
subst(new_value,old_variable,expression)
```

or

```
subst(old_variable=new_value, expression )
```

This command can also take a list of expressions and it performs the substitution in each of them.

## E.3. Trigonometric functions

Maxima implements all of the common trig functions and their inverses:
(1) $\boldsymbol{\operatorname { s i n }}(x), \boldsymbol{\operatorname { s i n }}(x)$ - the sine and its inverse.
(2) $\boldsymbol{\operatorname { c o s }}(\mathrm{x}), \operatorname{a\operatorname {cos}(\mathrm {x})-\text {thecosineanditsinverse.}}$
(3) $\boldsymbol{\operatorname { t a n }}(x), \boldsymbol{\operatorname { t a n }}(x)$ - the tangent and its inverse. We also have the $\operatorname{atan} 2(y, x)$ function, which computes the angle between the positive $x$-axis and a line from the origin and the point $(x, y)$. Note that $\operatorname{atan} 2(0, \mathrm{x})$ is 0 if $x>0$ and $\pi$ is $x<0 . \operatorname{atan} 2(0,0)$ is undefined.

## E.4. Logical Operations

We have already seen the if (something) then do_something construct. Variables can take on logical values: true, false. We also operations
$\triangleright$ and
$\triangleright$ or
$\triangleright$ not
$\triangleright$ is (expression) - determines whether expression is true. Returns true or false.

EXAMPLE. $\mathbf{i f}((\mathrm{a}<3)$ and $(\mathrm{b}>4))$ then do_something

## E.5. Looping constructs

Many programs have loops that perform sequences of computations over and over again. Maxima has several of these:
$\triangleright$ for variable: initial_value step increment thru limit do (body) Example: for t:0 step .01 thru 10 do (stuff)
$\triangleright$ for variable: initial_value step increment while logical_condition do (body)
for $\mathrm{x}: 1$ step 10 while keep_going do
(stuff,more_stuff,etc.,keep_going:(a>5))
$\triangleright$ for variable: initial_value step increment unless logical_condition do (body)
for $\mathrm{x}: 1$ step - 1 unless time_to_stop do
(stuff,more_stuff,etc.,time_to_stop:true)
$\triangleright$ while logical_condition do (stuff)
Predicate functions. These all end with the letter ' p ' and test properties of objects:
evenp - tests whether a literal integer is even. So evenp(2) is true, but if $x: 2 ; \operatorname{evenp}(x)$ is false.
integerp - tests whether a literal integer is present. So integerp(3) is true, but $x: 7$; integerp $(x)$ is false.
oddp - tests whether a literal integer is odd. So oddp(3) is true, but if $\mathrm{x}: 3$; $\mathbf{o d d p}(\mathrm{x})$ is false.
listp - tests whether an object is a list.
orderlessp - a predicate that takes two arguments and tests whether the first is less than the second. This uses an ordering that Maxima establishes for all identifiers and expressions (so all pairs of objects are comparable). This is not necessarily the same as numeric comparison (even between numbers).
ordergreatp - reverses orderlessp.
ordermagnitudep - compares numbers numerically (as $<$ ) and everything else like orderlessp.

## Exercises.

1. Since integerp only works for literal integers, how do you determine whether a variable like x is an integer?

## E.6. Lists

Since Maxima is written in Lisp, it has all of the powerful list-handling features of Lisp. A Maxima list is a comma-separated list ${ }^{1}$ of data-items enclosed in square brackets. Examples:

```
L1:[1,2,3]
L2:[[1],[[2]],x^2-1]
E:[]
```

Elements are accessed by indices that start with 1, in square brackets.

$$
\begin{aligned}
& \triangleright \text { L1[2] }=2 \\
& \triangleright \text { L2[3] }=x^{\wedge} 2-1 \\
& \triangleright \text { L2[2][1]=[2] }
\end{aligned}
$$

We have many other list-operations:
$\triangleright$ append returns the concatenation of all of the lists that occurs as its arguments. if list_1=[x_1,...x_n], list2=[y_1,...,y_m],...list_t=[w_1,...,w_k] then append(list_1,..., list_t)=[x_1,...x_n,y_1,...,y_m,...,w_1,...,w_k]
$\triangleright \operatorname{assoc}(k e y$, e, default) or assoc (key, e) - assoc searches for key as the first part of an argument of $e$ and returns the second part of the first match, if any.

- key may be any expression. $e$ must be a nonatomic expression, and every argument of $e$ must have exactly two parts. assoc returns the second part of the first matching argument of $e$. Matches are determined by is $(k e y=\operatorname{first}(a))$ where $a$ is an argument of $e$.

[^45]- If there are two or more matches, only the first is returned. If there are no matches, default is returned, if specified. Otherwise, false is returned.
Examples:
- $\operatorname{assoc}\left(f(x), f o o\left(g(x)=y, f(x)=z+1, h(x)=2^{*} u\right)\right)$;
$\mathrm{z}+1$
- assoc (yy, [xx = 111, yy = 222, yy = 333, yy = 444]); 222
- If there are no matches, default is returned, if specified. Otherwise, false is returned.
assoc (abc, [[x, 111], [y, 222], [ $z, 333]]$, none);
none
- assoc (abc, [[x, 111], [y, 222], [z, 333]]);
false
$\triangleright \operatorname{cons}(e, L)$ returns a new list with $e$ as the first element followed by the elements of $L$. Since it doesn't modify the list, $L$, one must write $L: \operatorname{cons}(e, L)$ to put a new element onto the list. This function can also be used where the second argument is other than a list, which might be useful. In this case, cons (expr_1, expr_2) returns an expression with same operator as expr_2 but with argument cons(expr_1, args(expr_2)).
Examples:
- cons(a,[b,c,d]);

$$
[\mathrm{a}, \mathrm{~b}, \mathrm{c}, \mathrm{~d}]
$$

- cons(a,f(b,c,d));
$f(a, b, c, d)$
$\triangleright$ create_list - create_list (form, $x_{-} 1$, list_1, $\left.\ldots, x \_n, l i s t \_n\right)$ Create a list by evaluating form with $x_{-} 1$ bound to each element of list_1, and for each such binding bind $x_{-} 2$ to each element of list_2, $\ldots$ The number of elements in the result will be the product of the number of elements in each list. Each variable $x_{-} i$ must actually be a symbol - it will not be evaluated. The list arguments will be evaluated once at the beginning of the iteration.
- create_list ( $\mathrm{x}^{\wedge} \mathrm{i}, \mathrm{i},[1,3,7]$ );
$\left[\mathrm{x}, \mathrm{x}, \wedge 3, \mathrm{x}^{\wedge} 7\right]$
- create_list ([i, j], i, [a, b], j, [e, f, h]);
[ [a, e], [a, f], [a, h], [b, e], [b, f], [b, h]]
$\triangleright$ copylist(list) Does what the name implies.
$\triangleright$ delete(expr_1, expr_2) removes from expr_2 any arguments of its top-level operator which are the same (as determined by "=") as expr_1. Note that " $=$ " tests for formal equality, not equivalence. Note also that arguments of subexpressions are not affected. Examples:
- Removing elements from a list.
(\%i1) delete ( $y,[w, x, y, z, z, y, x, w]$ );
(\%o1) [w, x, z, z, x, w]
- Removing terms from a sum.
(\%i1) delete $(\sin (x), x+\sin (x)+y)$;
(\%o1) $y+x$
- Removing factors from a product.
(\%i1) delete $\left(u-x,(u-w)^{*}(u-x)^{*}(u-y)^{*}(u-z)\right)$;
(\%o1) (u-w) (u-y) (u-z)
- Removing arguments from an arbitrary expression.
(\%i1) delete ( a , foo ( $\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}, \mathrm{a}$ ));
(\%o1) foo(b, c, d)
- Limiting the number of removed arguments.
(\%i1) delete ( a , foo ( $\mathrm{a}, \mathrm{b}, \mathrm{a}, \mathrm{c}, \mathrm{d}, \mathrm{a}$ ), 2);
(\%o1) foo(b, c, d, a)
$\triangleright$ endcons $(e, L)$ returns a new list with all of the elements of $L$ followed by $e$. The second argument ( $L$ ) can also be an expression. Since it doesn't modify the list, $L$, one must write $L$ :endcons $(e, L)$ to put a new element onto the front of the list. Examples:
- (\%i1) endcons( $\mathrm{a},[\mathrm{b}, \mathrm{c}, \mathrm{d}]$ );
(\%o1) [b, c, d, a]
- (\%i2) endcons( $\mathrm{a}, \mathrm{f}(\mathrm{b}, \mathrm{c}, \mathrm{d})$ );
(\%o2) f(b, c, d, a)
$\triangleright$ first(expr) - Returns the first part of expr which may result in the first element of a list, the first row of a matrix, the first term of a sum, etc.
$\triangleright$ firstn (expr, count) - Returns the first count arguments of expr, if expr has at least count arguments. Returns expr if expr has less than count arguments.
$\triangleright$ join $(L, m)$ - Creates a new list containing the elements of lists $L$ and $m$, interspersed. The result has elements [L[1], $m[1], L[2]$, $m[2], \ldots]$. The lists $L$ and $m$ may contain any type of elements.
$\triangleright$ last (expr) — Returns the last part (term, row, element, etc.) of the expr.
$\triangleright$ lastn (expr, count) —— Returns the last count arguments of expr, if expr has at least count arguments. Returns expr if expr has less than count arguments.
$\triangleright$ length (expr) — Returns (by default) the number of parts in the external (displayed) form of expr. For lists this is the number of elements, for matrices it is the number of rows, and for sums it is the number of terms.
$\triangleright \operatorname{map}(f, l i s t)$ - returns a list with the function $f$ applied to the members of list.
$\triangleright$ listp (expr) - Returns true if expr is a list else false.
$\triangleright$ lreduce $(F, s)$ - extends the binary function, $F$, to all of the list, $s$, by composition from the left. Example
lreduce $\left.(F, s)=F\left(\ldots F\left(s \_1, s \_2\right), s \_3\right), s \_4, \ldots, s \_n\right)$.
$\triangleright$ makelist - makelist (), creates the empty list, [].
- makelist (expr, $n$ ), makelist (expr), creates a list with expr as its single element. makelist (expr, $n$ ) creates a list of $n$ copies of expr.
- makelist $\left(\operatorname{expr}(i), i, i \_\max \right)$ creates a list with expr evaluated at $i=1$ to $i=i m a x$, stepped by 1 each time.
- makelist $\left(\operatorname{expr}(i), i, i \_0, i \_\max \right)$ creates a list with $\operatorname{expr}$ evaluated at $i=i 0$ to $i=i m a x$, stepped by 1 each time.
- makelist (expr(i), i, i_0, i_max, step) creates a list with expr evaluated at $i=i 0$ to $i=i m a x$, stepped by step each time.
- makelist $(\operatorname{expr}(x), x, l i s t)$ creates a list with $\operatorname{expr}(x)$ evaluated $\mathbf{x}$ equal to successive elements of list.
$\triangleright$ member (expr_1, expr_2) Tests whether expr_1 is a member of expr_2, which may be a list or expression.
$\triangleright$ pop (list) - removes and returns the first element of list. Note: it modifies list in the process.
push (item, list) - puts item as the first member of list and returns a copy of the new list.
$\triangleright$ rest - rest (expr, $n$ ) rest (expr) Returns expr with its first $n$ elements removed if $n$ is positive and its last $-n$ elements removed if $n$ is negative. If $n$ is 1 it may be omitted. The first argument expr may be a list, matrix, or other expression. Applying rest to expression such as $f(a, b, c)$ returns $f(b, c)$. In general, applying rest to a nonlist doesn't make sense. For example, because ' $\wedge$ ' requires two arguments, $\boldsymbol{r e s t}\left(\mathrm{a}^{\wedge} \mathrm{b}\right)$ results in an error message. The functions args and op may be useful as well, since $\operatorname{args}\left(a^{\wedge} b\right)$ returns $[a, b]$ and $\mathbf{o p}\left(\mathrm{a}^{\wedge} \mathrm{b}\right)$ returns ${ }^{\wedge}$.
$\triangleright$ reverse (list) — Reverses the order of the members of the list (not the members themselves). reverse also works on general expressions, e.g. reverse( $a=b$ ); gives $b=a$.
$\triangleright \operatorname{rreduce}(F, s)$ - Like lreduce but it works from the right rather than the left. Example:
rreduce $(F, s)=F\left(s \_1, F\left(s_{-} 2, \ldots F\left(s \_(n-2), F\left(s \_(n-1), s \_n\right) \ldots\right)\right.\right.$.
$\triangleright \operatorname{sort}($ list, predicate $)$ - returns a list that is the result of sorting list in ascending order, using the predicate to compare pairs of items. If predicate is omitted, then orderlessp is used (which can compare any two Maxima objects or expressions). To sort in descending order, use ordergreatp as the predicate.
The predicate may be specified as the name of a function or binary infix operator, or as a lambda expression. If specified as the name of an operator, the name must be enclosed in double quotes.
- sort ([1, a, b, 2, 3, c], 'orderlessp);
[1, 2, 3, a, b, c]
- $\boldsymbol{\operatorname { s o r t }}$ ([1, a, b, 2, 3, c],'ordergreatp); [c, b, a, 3, 2, 1]
- L: [\%pi, 3, 4, \%e, \%gamma];
[\%pi, 3, 4, \%e, \%gamma]
sort (L, ">");
[4, \%pi, 3, \%e, \%gamma]
- ordermagnitudep orders numbers, constants, and constant expressions the same as <, and all other elements the same as orderlessp.

L: [\%i, 1+\%i, $\left.2^{*} x, \operatorname{minf}, \inf , \% e, \sin (1), 0,1,2,3,1.0,1.0 b 0\right] ;$
[\%i, \%i + 1, $2 \mathrm{x}, \mathrm{minf}, \mathrm{inf}, \% \mathrm{e}, \sin (1), 0,1,2,3,1.0,1.0 \mathrm{~b} 0]$
sort (L, ordermagnitudep);
[minf, $0, \sin (1), 1,1.0,1.0 b 0,2, \% e, 3, i n f, \% i, \% i+1,2 x]$
$\triangleright$ sublist (list, $p$ ) — Returns the list of elements of list for which the predicate $p$ returns true.
L: $[1,2,3,4,5,6]$;
[1, 2, 3, 4, 5, 6]
sublist (L, evenp);
[2, 4, 6]
$\triangleright$ sublist_indices (L, P) - Returns the indices of the elements $x$ of the list $L$ for which the predicate maybe $(P(x))$ returns true; this excludes unknown as well as false. $P$ may be the name of a function or a lambda expression. $L$ must be a literal list.

- sublist_indices ('[a, b, b, c, 1, 2, b, 3, b], lambda ([x], x='b)); [2, 3, 7, 9]
$\triangleright$ tree_reduce - tree_reduce $(F, s)$, tree_reduce $\left(F, s, s \_0\right)$ Extends the binary function $F$ to an $n$-ary function by composition, where $s$ is a set or list.
- tree_reduce is equivalent to the following: Apply $F$ to successive pairs of elements to form a new list [F(s_1, s_2), F(s_3, $\left.\left.s \_4\right), \ldots\right]$, carrying the final element unchanged if there are an odd number of elements. Then repeat until the list is reduced to a single element, which is the return value.
- When the optional argument s_0 is present, the result is equivalent tree_reduce $\left(F\right.$, cons $\left(s \_0, s\right)$ ).
$>$ unique $(L)$ - Returns the unique elements of the list $L$.
- When all the elements of $L$ are unique, unique returns a shallow copy of $L$, not $L$ itself.
- If $L$ is not a list, unique returns $L$.

## E.7. Macros

To describe what a macro does, we must first analyze how a function is called. When $f(x, y, z)$ is called, Maxima
(1) evaluates $x, y, z$
(2) jumps to the function-code and plugs those values into the body of $f$.
(3) then returns with the computed values

A macro $f(x, y, z)$ superficially resembles a function but it
(1) executes the body of the macro on $x, y, z$ and other expressions (doing something like a text-edit), inserting it into the code where that called it - i.e., no jumping and returning,
(2) then it executes the revised expression.

A user-defined macro uses the ::= operation:

```
zz(x)::=x / 10;
```

The right side of this is edited into the expression where

```
zz(x)
```

appears. In other words
p: a+b+zz (top) +d
is rewritten into
p:a+b+top $/ 10+d$
before it is executed. As such, the effect of this macro is very similar to a function-call.

The main macro built in to Maxima is buildq. It has the form

```
buildq([x1:vq, x2:v2,...,xn:vn],
    stuff involving x1,\ldots,xn
    );
```

It does a kind of text-edit of stuff replacing xi by vi for $i=1, \ldots, n$, and then it executes the edited code. If an xi has no corresponding vi, whatever value it was assigned in the past is used. So

```
b:29;
buildq ([a: x, b], a + b + c);
```

results in
$\mathrm{x}+\mathrm{c}+29$
The command

```
buildq ([e: [a, b, c]], foo (x, e, y));
```

results in
foo (x, [a, b, c], y)
which is then executed.
Note that the substitutions a buildq command are carried out in parallel, so

```
buildq ([a:x,b:a,c,b], foo (x, e, y));
```

## produces

```
foo (x, a, b);
```

If they had been carried out sequentially (from left to right, as subst does), we would've gotten
foo ( $\mathrm{x}, \mathrm{x}, \mathrm{x}$ );
Within a buildq command, the splice-command (whose argument is a list) interpolates that list into a larger list. So, whereas,
buildq ([e: [a, b, c]], foo (x, e, y));
produces
foo (x, [a, b, c], y)
the splice command
buildq ([e: [a, b, c]], foo (x, splice(e), y));
produces

$$
\text { foo }(x, a, b, c, y)
$$

Outside of a buildq command, the splice-command is merely an error.
Here's an example that combines several language features:

$$
\text { show_values ([L]) ::= buildq ([L], map } \left.\left("=", \quad \mathrm{~L}, \mathrm{~L}^{\mathrm{L}} \mathrm{~L}\right)\right) \text {; }
$$

If we have statements

```
a:3;
b:2;
c:1000;
print(show_values(a,b,c));
```

is interpreted in several steps. First, it rewrites the print statement as

$$
\text { print(buildq }([a, b, c], \operatorname{map}("=", \quad[a, b, c],[a, b, c]))) ;
$$

Next, we get

```
print(map ("=", '[a,b,c], [a,b,c])));
```

Since the print command is a function rather than a macro, it executes the map-command to get

```
print([a=2,b=3,c=1000]);
```

and prints it.
Other macro-related commands, include
macroexpand - this expands a macro but doesn't execute it. If the macro calls other macros, they are also expanded.
macroexpand1 - this expands a macro but doesn't execute it. If the macro calls other macros, they are not expanded - it only expands the topmost level of nested macro-calls.

## E.8. Input and Output

The most widely-used forms of output involve plotting and drawing pictures. These operations are so important, an entire appendix is devoted to them - see appendix F on page 251.

Simple (and useful for debugging) output-commands are:
$\triangleright$ display (expr_1, expr_2,...) — displays equations whose left side is expr_i unevaluated, and whose right side is the value of the expression centered on the line. This function is useful in blocks and for statements in order to have intermediate
results displayed. The arguments to display are usually atoms, subscripted variables, or function calls.
$\triangleright$ print (expr_1, ..., expr_n) - Evaluates and displays expr_1,..., expr_ $n$ one after another, from left to right, starting at the left edge of the console display. The value returned by print is the value of its last argument. print does not generate intermediate expression labels.
Note: __ (two underscores) represents the input expression currently being evaluated. That is, while an input expression expr is being evaluated, $\qquad$ is expr. Example:

- print ("My name is ",__);

My name is print(My name is, __)

- zztop (__);
zztop(zztop(__))
$\triangleright$ appendfile (filename) - Appends a console transcript to filename. appendfile is the same as writefile, except that the transcript file, if it exists, is always appended.
$\triangleright$ batchload (filename) - Reads Maxima expressions from filename and evaluates them, without displaying the input or output expressions and without assigning labels to output expressions. Printed output (such as produced by print or describe) is displayed, however.
$\triangleright$ closefile() closes the transcript file opened by appendfile or writefile.
$\triangleright$ file_search (filename) - file_search searches for the file filename and returns the path to the file (as a string) if it can be found; otherwise file_search returns false. file_search (filename) searches in the default search directories, which are specified by the file_search_maxima, file_search_lisp, and file_search_demo variables.
file_search first checks if the actual name passed exists, before attempting to match it to "wildcard" file search patterns.
- file_search_maxima Option variable,
- file_search_lisp Option variable,
- file_search_demo Option variable,
- file_search_usage Option variable,
- file_search_tests.
$\triangleright$ load - load (filename) Evaluates expressions in filename, thus bringing variables, functions, and other objects into Maxima. The binding of any existing object is clobbered by the binding recovered from filename. To find the file, load calls file_search with file_search_maxima and file_search_lisp as the search directories. If load succeeds, it returns the name of the file. Otherwise load prints an error message.
- load works equally well for Lisp code and Maxima code. Files created by save, translate_file, and compile_file, which create Lisp code, and stringout, which creates Maxima code,
can all be processed by load. load calls loadfile to load Lisp files and batchload to load Maxima files.
$\triangleright$ directory - directory (path) Returns a list of the files and directories found in path in the file system. path may contain wildcard characters (i.e., characters which represent unspecified parts of the path), which include at least the asterisk on most systems, and possibly other characters, depending on the system.
$\triangleright$ printfile - printfile (path) Prints the file named by path to the console. path may be a string or a symbol; if it is a symbol, it is converted to a string. If path names a file which is accessible from the current working directory, that file is printed to the console. Otherwise, printfile attempts to locate the file by appending path to each of the elements of file_search_usage via filename_merge. printfile returns path if it names an existing file, or otherwise the result of a successful filename merge.
$\triangleright$ save -This takes several forms:
- save (filename, name_1, name_2, name_3,...) Stores the current values of name_1, name_2, name_3, ..., in filename. The arguments are the names of variables, functions, or other objects. If a name has no value or function associated with it, it is ignored. save returns filename. save stores data in the form of Lisp expressions. If filename ends in .lisp the data stored by save may be recovered by load (filename). See load.
- save (filename, values, functions, labels, ...) - stores the items named by values, functions, labels, etc. The names may be any specified by the variable infolists.values comprises all userdefined variables.
- save (filename, $[m, n]$ ) - stores the values of input and output labels $m$ through $n$. Note that $m$ and $n$ must be literal integers. Input and output labels may also be stored one by one, e.g., save ("foo.1", \%i42, \%o42).
- save (filename, labels) stores all input and output labels. When the stored labels are recovered, they clobber existing labels.
- save (filename, all) - stores the current state of Maxima.
- save (filename, name_1=expr_1, name_2=expr_2,...) stores the values of expr_1, expr_2, ..., with names name_1, name_2, ... It is useful to apply this form to input and output labels, e.g., save ("foo.1", aa=\%o88). The right-hand side of the equality in this form may be any expression, which is evaluated.
$\triangleright$ stringout — Similar to save above but stores information in Maxima form rather than Lisp form. This occurs in several forms (see save, above):
- stringout (filename, expr_1, expr_2, expr_3, ...)
- stringout (filename, [m, n])
- stringout (filename, input)
- stringout (filename, functions)
- stringout (filename, values)
$\triangleright$ with_stdout - with_stdout (s, expr_1, expr_2, expr_3, ...) Evaluates expr_1, expr_2, expr_3, $\ldots$ and writes any output thus generated to a file $f$ or output stream $s$. The evaluated expressions are not written to the console. with_stdout redirects output commands that normally print on the console to the file. Output may be generated by print and display among other functions.
with_stdout ("tmp.out", for i:5 thru 10 do
print (i, "! yields", i!))\$
(\%i2) printfile ("tmp.out")\$
5 ! yields 120
6 ! yields 720
7 ! yields 5040
8 ! yields 40320
9 ! yields 362880
10 ! yields 3628800
$\triangleright$ writefile - writefile(filename) Begins writing a transcript of the Maxima session to filename. All interaction between the user and Maxima is then recorded in this file, just as it appears on the console.

## APPENDIX F

## Visual outputs

## F.1. Plotting

F.1.1. Basic plot-commands. Basic plotting in wxMaxima is done by external software called 'gnuPlot', which provides the commands plot2d and plot3d as well as several others. The basic command varies depending on whether you are doing a single plot or multiple superimposed plots.

With a single plot, the format looks like ( $\mathrm{z}=2,3$ )

```
plotzd(function_specification ,[x,lower_lim,upper_lim]
{,[y, lower_lim,upper_lim ]}
{,[style, plot_options]}{,terminal_spec }{,file_spec })
```

(Items in curly brackets are optional).
With multiple superimposed plots (only with plot2d) we have

```
plot2d([f1,\ldots.,fn],[x,lower_lim,upper_lim ]
{,[y, lower_lim,upper_lim]},
{[style, plot_option_1,\ldots., plot_option_n]}
{,terminal_spec}{, file_spec })
```

F.1.2. Function specifications. Descriptions of functions to be plotted take many forms. The most basic function-specification is simply to name the function. Examples:
$\triangleright x^{\wedge} 2-3^{*} x$
$\triangleright \sin (\cos (\mathrm{x}))$
In many cases, functions are defined by Maxima code that has an if-statement that tests the independent variable. In these cases, the function must be quoted with a single quote. Example:
$\triangleright$ 'myfunct(x)
With functions like this, the if-statement is evaluated once by Maxima and the outcome remains fixed throughout the plot. The solution is to quote the function, so the function itself is sent to GnuPlot.
$\triangleright$ With functions only defined at certain points, we can define a function to be discrete. This consists of the keyword discrete in a list with a list of points. For example:
f:[discrete,[[1,2],[2,3],[3,5],[4,7],[5,11],[6,13],[7,17],[8,19],[9,23],[10,29]]];
defines a function equal to the first 10 prime numbers. In general, a discrete function can take two forms:
[discrete,[[x1,y1],...,[xn,yn]]] or
[discrete,[[x1,.., xn],[y1,...,yn]]]
$\triangleright$ An equation defines an implicit function, and these can be plotted.
One must provide ranges of values for all the variables. Example: $\operatorname{plot} 2 d\left(x^{\wedge} 2+y^{\wedge} 4=1,[x,-1,1],[y,-1,1]\right)$.
F.1.3. High-level plot styles. These are specified with the word 'style' followed in a list that indicates the style:
$\triangleright$ lines - this is the default. Points are plotted and connected with lines.
$\triangleright$ points — plots isolated points.
$\triangleright$ linespoints - plots lines but also highlights the original points.
$\triangleright$ dots - plots isolated dots.
Example:
[style,lines,lines,points] if are plotting three functions and want these three respective styles.

We also specify colors of the various plots via:
[color,name_1,...,name_n]
for n plots. The acceptable colors-names are
$\triangleright$ red
$\triangleright$ green
$\triangleright$ blue
$\triangleright$ magenta
$\triangleright$ cyan
$\triangleright$ yellow
$\triangleright$ orange
$\triangleright$ violet
$\triangleright$ brown
$\triangleright$ gray
$\triangleright$ black
$\triangleright$ white
$\triangleright$ \# followed by six hexadecimal digits: two for the red component, two for green component and two for the blue component. This expression must be quoted with double-quotes. Example: "\#3d01f2". This produces a bluish violet color.
$\triangleright$ If the name of a given color is unknown, black is used
If there are more curves or surfaces than colors, the colors are repeated in sequence. For instance, if you write [color,black] all of the plots will be black. If no colors are specified, defaults are used (blue, red, green, etc.).

If we have points in the styles, we can specify the point type via the statement
[point_type,typename_1...,typename_n]
The acceptable point-type-names are:
$\triangleright$ bullet
$\triangleright$ circle
$\triangleright$ plus
$\triangleright$ times

Figure F.1.1. High-level plot example

```
\triangleright asterisk
box
 square
triangle
delta
 wedge
 nabla
diamond
& lozenge
```

If there are more sets of points than objects in this list, they will be repeated sequentially.

Here's an example:
plot2d ([ $x^{\wedge} 2, x^{\wedge} 3, x^{\wedge} 4,[$ discrete,$[[.1, .2],[.2, .3],[.3, .5]$, [.4,.7],[.5,.11],[.6,.13],[.7,.17],[.8,.19],[.9,.23], [1, .29]]]],[x,-1,1],[style, lines, lines, lines, points], [color, blue, red, green],[ point_type, nabla])

This produces the plot in figure F.1.1.
Another example: Here we plot two implicit functions, one explicit one $\left(x^{\wedge} 2\right)$ and a discrete function that is defined at a single point. Note that discrete functions expect a list of points even if there's only a single point in it:

```
plot2d([x=1,y=3,x^2,[discrete,[[1,3]]]],[x,-1,3],
[y, -1,10],[style,lines,lines,lines,points],
[point_type, asterisk]);
```

We get the plot in figure F.1.2 on the next page.

Figure F.1.2. Mixed plot-types
F.1.4. Slightly lower-level plot styles. These are slightly harder to use than the high-level options above. Their main (only?) advantage is that you can specify the size of each object. In this case, the styles are lists rather than simple names:
$\triangleright$ [lines,line_width\{,color\}] — this is the default. Points are plotted and connected with lines.
$\triangleright$ [points,radius_of_points\{,color,type_of_point\}] — plots isolated points. See table F.1.1 on the facing page.
$\triangleright$ [linespoints,line_width\{,color\}] - plots lines but also highlights the original points.
$\triangleright$ [dots] — plots isolated tiny dots.
For example:
plot2d([[discrete,[[-1,.3],[0,.1],[1,.5]]], $\left.x^{\wedge} 2\right]$,
[ $\mathrm{x},-1,1],[$ style ,[points , $4,7,1],[$ lines , 2,1$]])$;
produces the plot in figure F.1.3 on the next page.
If we leave out the style command, the style defaults to 'lines' and the plot looks like figure F.1.4 on the facing page.

Colors (X11 term)
1: blue, 2 : red, 3 : magenta, 4 : orange, 5 : brown, 6 : lime and 7: aqua
F.1.5. Other options. There are several other options that affect how the plot looks. These are all optional.
$\triangleright$ [nticks,nn] - the number of initial points used to calculate the curve (the default is 10 ). GnuPlot starts evaluating the function to be plotted with this number of points and subdivides its intervals

Figure F.1.3. Plot example 1

| Code | Description | Code | Description | Code | Description |
| :---: | :---: | :---: | :---: | :---: | :---: |
| -1 | None | 4 | Square | 9 | Filled up-triangle |
| 0 | Dot | 5 | Filled square | 10 | Down-triangle |
| 1 | Plus | 6 | Circle | 11 | Filled down-triangle |
| 2 | Multiply | 7 | Filled circle | 12 | Diamond |
| 3 | Asterisk | 8 | Up-triangle | 13 | Filled diamond |

TABLE F.1.1. type_of_point codes

Figure F.1.4. Plot example 2
where the function changes rapidly, the goal being to produce a smooth plot.
$\triangleright$ [xlabel,"text"] — label for the x-axis.

Figure F.1.5. Parametric plot 1
$\triangleright$ [ylabel,"text"] — label for the y-axis.
$\triangleright$ [legend,"text1",...,"textn"] - labels for n plots (must be in the same order as the plotted functions!).
$\triangleright$ [grid,nx,ny] — number of grid-lines.
$\triangleright$ [yxratio, nn] - defines the shape of the rectangle in which the plot is drawn.
$\triangleright$ [title,"string"] - the title of the plot.
$\triangleright \log x, \log y$ - not enclosed in square brackets. Causes logarithmic scales to be used.
$\triangleright$ same_xy - causes the aspect ratio of the plot to be 1.
Note. Some editors uses "styled" curly brackets for the quote character. These are not recognized as quotes by wxMaxima (although they display as straight quotes in wxMaxima!) and can lead to mysterious errors. Of course, using wxMaxima as your text-editor produces the right kinds of quotes!
F.1.6. Parametric plots. Many geometric objects are defined parametrically. These can be plotted with plot2d and a list headed with the keyword parametric. The general form is

```
plot2d ([parametric, two-functions_of_parameter,
range_of_parameter]);
```

For instance, the command

```
plot2d ([parametric, cos(t), sin(t), [t,-%pi,%pi]],
[x, -4/3, 4/3]);
```

produces the plot in figure F.1.5.
Parametric plots can be mixed with other types. For instance, the code in figure F.1.6 on the facing page produces the plot in figure F.1.7 on the next page.

```
plot2d ([x^2+2, [parametric, cos(t), sin(t),
[t, -5, 5]]], [x, -3, 3]);
```

Figure F.1.6. Code for mixed parametric plot

Figure F.1.7. Mixed parametric plot
F.1.7. Contour plots. This involves plotting contour lines for a function of two variables - these are like isobars on a weather map. The function to be plotted appears in a list whose first element is the keyword contour. Example:

```
plot2d ([contour, sin (y) * cos(x)^2],
[x, -4, 4], [y, -4, 4]);
```

which produces the plot in figure F.1.8 on the following page. This shows the level-sets for the function $f(x, y)=\sin (y) \cos (x)^{2}$ at $f=-0.5,0,0.5$.

## F.2. plot3d

Many of the options for plot2d also apply to plot3d. Other options include nomesh_lines.
plot3d (expr, $x_{-}$range, $y_{-}$range, ..., options,...)
Example:

```
plot3d (u^2 - v^2, [u, -2, 2], [v, -3, 3],
    [grid, 100, 100],
    nomesh_lines);
```

This produces the plot in figure F.2.1 on the next page.

Figure F.1.8. Contour plot

Figure F.2.1. A 3d plot

If we leave out the nomesh_lines, we get figure F.2.2 on the facing page (so mesh lines are the default).

Other options:
$\triangleright$ elevation - the z-values are compressed or expanded to this range. Setting [elevation,0] smashes the three-dimensional plot to two dimensions. See figure F.2.3 on the next page.
$\triangleright$ palette - the set of colors to use in the plot. For instance, the command in figure F.2.4 on the facing page produces the plot in figure F.2.5 on page 260. The gradient option causes the colors
z

Figure F.2.2. A 3d plot with mesh

Figure F.2.3. Plot with elevation 0

```
plot3d (u^2 - v^2, [u, -2, 2], [v, -3, 3],
    [palette, [gradient, red, orange,
        yellow, green]],
    [grid, 100, 100]);
```

Figure F.2.4. Plot using palette

Figure F.2.5. Plot with a color palette

Figure F.2.6. Plot with a color-bar
to smoothly transition from low z -values (red) to high z -values (green). There is also a color_bar option that draws the palette and gives one an idea of what the colors mean. Adding that option gives the plot in figure F.2.6 on page 260.

Figure F.3.1. The Mandelbrot set

## F.3. Standalone commands

We have two specialized plot commands that can to create graphic objects.
$\triangleright$ julia ( $\mathrm{x}, \mathrm{y}, \ldots$ options...) - creates a Julia set for the complex number $x+i y$. Each pixel in the grid is given a color corresponding to the number of iterations it takes the sequence that starts at that point to move out of the convergence circle of radius 2 centered at the origin. The number of pixels in the grid is controlled by the grid plot option (default 30 by 30 ). The maximum number of iterations is set with the option iterations.
$\triangleright$ mandelbrot (options). - Draws a Mandelbrot set with the same options as Julia. For instance, the command

```
mandelbrot ([iterations, 30], [x, -2, 1],
    [y, -1.2, 1.2],
    [grid,400,400])
```

produces the plot in figure F.3.1.

## F.4. Plot-outputs

Gnuplot generates plots on 'terminals'. If no terminal is specified, it defaults to 'x11term', the computer screen. Other terminals include:
$\triangleright$ dumb - tries to do the plot in ASCII-art!
$\triangleright$ ps - creates the plot in Postscript, suitable for printing. All of the plots in this book were done on the ps terminal.

```
with_slider_draw(
    t, /*variable to attach to the slider */
    makelist(j,j,0,100), /* list of integers */
    explicit(psi_n(100,x,.01*t),x,-%pi,%pi),
    /*plot */
    yrange= [0,1.2] /*optional graphic command */
    ); /* end of with_slider_draw-command */
```

Figure F.5.1. The with_slider_draw command
$\triangleright \operatorname{svg}$ — Scalable Vector Graphics, best for displaying on web pages. These images can be easily resized without losing information (which is why they're called 'scalable').
$\triangleright$ png — Portable Network Graphics, a bitmapped format for web pages.
$\triangleright$ jpg — A lossy, compressed format, suitable for web pages (jpg files for an image are much smaller than png ones for the same image - sometimes by a factor of 100). This format uses two-dimensional, discrete Fourier transforms - see section 5.1 on page 75 .
$\triangleright$ pdf — Portable document format, also good for printing.
This is specified via the command:
[gnuplot_term,"terminal_name"]
One can also specify an output file in square brackets and quotes, like the terminal. The command:
[gnuplot_out_file,"filename"]
Example:

```
plot2d(x^2,[x,-5,5],[gnuplot_term, "svg"],
    [gnuplot_out_file," zz.svg"])
```

## F.5. The draw commands

The draw-library contains commands that are much more complex than those of plot2d and plot3d, but allow more complete access to gnuPlot's features. We have already seen one command of this library in section 4.5 on page 61, namely figure F.5.1

Although the draw-library is supposed to be loaded via the

```
load("draw")
```

command, this author has found that the draw-commands work without explicitly loading this library, suggesting that it is loaded by default.

The basic command appears in figure F.5.2 on the facing page.
Global options apply to all of the scenes and include:
$\triangleright$ terminal - the type of output. The terminals in the draw-library are:

```
draw(
    global_options,
    scene_1,
    scene_2,
    scene_n
);
```

Figure F.5.2. Basic draw-command

- screen (default) - the computer screen. Can, optionally, be coded as [screen, $n n$ ], where $n n$ is a number. This allows multiple windows with plots to be opened at the same time.
- png - Portable Network Graphics. A bitmapped format.
- pngcairo - Portable Network Graphics using the Cairo library (if it's present). A bitmapped format that uses antialiasing to produce a clearer image.
- jpg - A compressed, lossy format.
- gif - A compressed format with a limited number of colors.
- eps - Encapsulated postscript in black and white (if your output is meant to be printed, it will probably be in black and white anyway). eps is like postscript except that the file has the size of the image specified so it can be displayed with a minimum of white space around it. The postscript files generated by the plot commands are actually eps.
- eps_color - Encapsulated postscript in all its colorful glory.
- epslatex - Encapsulated postscript and LATEX code to insert it into a $\mathrm{EAT}_{\mathrm{E}} \mathrm{X}$ document.
- epslatex_standalone - Encapsulated postscript and a LATEX document to display it.
- svg - Scalable vector graphics. Ideal for web pages.
- canvas - Produces an html file with the graphics, using the Canvas and gnuPlot javascript libraries. Good for web pages, although most browsers support SVG.
- dumb - ASCII art!
- dumb_file - ASCII art in a file!
- pdf - produces a PDF document.
- pdfcairo - same as above but uses the Cairo library to produce an antialiased image.
- wxt - an alternate drawing library. On many systems, this is a synonym for screen.
- animated_gif - the gif format allows for animated images.
- multipage_pdfcairo - like pdfcairo but spanning multiple pages.
- multipage_pdf - like pdf but spanning multiple pages.
- multipage_eps - like eps but spanning multiple pages.
- multipage_eps_color - like eps_color but spanning multiple pages.
- aquaterm - aquaterm is a graphics terminal for the Macintosh running MacOS X. Can, optionally, be coded as [aquaterm, $n n$ ], where $n n$ is a number. This allows multiple windows with plots to be opened at the same time.
$\triangleright$ file_name - as mentioned in section F. 4 on page 261, except that the draw library adds its own extension to the name, like 'pdf', or 'eps' so you don't have to.
$\triangleright$ columns - each scene produces a plot, and multiple plots are normally stacked on top of each other. columns $>1$ allows multiple plots to appear side by side.
These are coded as option=value rather than in a list. Values that are not arbitrary character strings do not need to be quoted ${ }^{1}$ unless they are used as variables in the rest of your program ${ }^{2}$ in which case they can be quoted with a single, single quote like 'eps. Example:

```
draw(
    gr2d(
        key=" sin (x)",grid=[2,2],
        explicit(
            sin(x),
            x,0,2*% pi
        )
    ),
    gr2d(
        title="zztop",
        key="cos (x)",grid=[2,2],
        explicit(
            cos(x),
            x,0,2*% pi
        )
    )
);
```

This produces two smaller plots, one on top of the other - see figure F.5.4 on the facing page. If we set the global option columns=2, and type the command in figure F.5.3 on the next page, we get the plots side-by-side and compressed horizontally in figure F.5.5 on the facing page.

Scenes may take one of two forms:
$\triangleright \operatorname{gr2d}$ (options) — for a two-dimensional scene. The available options (besides a function to be plotted) are

- bars ([x1,h1,w1], [x2,h2,w2, ...]) - draws bars centered at values $\mathrm{x} 1, \mathrm{x} 2, \ldots$ with heights $\mathrm{h} 1, \mathrm{~h} 2, \ldots$ and widths $\mathrm{w} 1, \mathrm{w} 2, \ldots$ Options: color (see table F.5.1 on page 269 for color-names).

[^46]```
draw(
    columns=2,
    gr2d(
            key=" sin (x)",grid=[2,2],
            explicit(
                sin(x),
                x,0,2*% pi
        )
    ),
    gr2d(
        title="zztop",
        key="cos (x)",grid=[2,2],
        explicit(
            cos(x),
            x,0,2*% pi
        )
    )
);
```

Figure F.5.3. Two-column plot

FIGURE F.5.4. Drawing two plots in one command

Figure F.5.5. Drawings with two columns

- ellipse (xc, yc, a, b, ang1, ang2) - plots an ellipse centered at [ $x c, y c$ ] with horizontal and vertical semi axis $a$ and $b$, respectively, starting at angle ang1 and ending at angle ang2. Options: transparent (= true or false), fill_color, border (= true
or false), line_width, key, line_type and color (see table F.5.1 on page 269 for color-names).
- explicit
- image
- implicit
- key - the draw-version of "legend." key = "string".
- parametric (xfun,yfun,par,parmin,parmax).
- points ([[x1,y1], [x2,y2],..]] - Options: point_size, point_type, points_joined (= true or false), line_width, key, line_type and color (see table F.5.1 on page 269 for color-names). Point_types: bullet, circle, plus, times, asterisk, box, square, triangle, delta, wedge, nabla, diamond, lozenge.
- polar (radius,ang,minang,maxang) Options color, line_width, (see table F.5.1 on page 269 for color-names).
- polygon ([x1, x2,...], [y1, y2, ...]) or polygon ([[x1, y1], [x2, y2], ...]) - Options color, fill_color, line_width, border (= true or false) (see table F.5.1 on page 269 for color-names).
- quadrilateral([x1, y1], [x2, y2], [x3, y3], [x4, y4]) - Options: transparent (= true or false), fill_color, border (= true or false), line_width, key, xaxis_secondary, yaxis_secondary, line_type, transform and color (see table F.5.1 on page 269 for color-names).
- title = "string".
- rectangle ([x1,y1], [x2,y2]) - The points are opposite vertices. Options: transparent (= true or false), fill_color, border (= true or false), line_width, key, line_type and color (see table F.5.1 on page 269 for color-names).
- triangle ([x1,y1], [x2,y2], [x3,y3]) - Options: transparent (= true or false), fill_color, border (= true or false), line_width, key, line_type and color (see table F.5.1 on page 269 for colornames).
- vector([ $[\mathrm{x}, \mathrm{y}],[\mathrm{d} x, \mathrm{dy}])$ - plots vector $[\mathrm{d} x, \mathrm{dy}]$ with origin in [ $x, y$ ]. Options: head_both (= true or false), head_length, head_angle, head_type, line_width, line_type, key and color (see table F.5.1 on page 269 for color-names).
The options explicit or implicit are required if functions are plotted. plot2d automatically decided whether a plot is explicit or implicit by how one codes it. The draw-library requires you to specify. Multiple functions can be plotted in the same scene (as the code in figure F.5.6 on the facing page shows), in which case they will overlap each other (see figure 13.2.2 on page 223 for an example of this).
gr3d(options) - for a three-dimensional scene. The available options are:
- cylindrical(radius, z, minz, maxz, azi, minazi, maxazi) plots the function radius(z, azi) defined in cylindrical coordinates, with variable $z$ taking values from minz to maxz

```
draw (
    gr2d
        explicit
            \(\sin (x)\),
            x, \(0,2 * \%\) pi
        )
        explicit
            \(\cos (x)\),
            \(x, 0,2 * \%\) pi
        )
    )
);
```

Figure F.5.6. Multiple functions in the same scene
and azimuth azi taking values from minazi to maxazi. Options: xu_grid, yv_grid, line_type, key, wired_surface, enhanced3d and color (see table F.5.1 on page 269 for colornames).

- elevation_grid (mat,x0,y0,width,height) - draws matrix mat in 3D space. z values are taken from mat, the abscissas range from x 0 to $\mathrm{x} 0+$ width and ordinates from y 0 to $\mathrm{y} 0+$ height. Element $\mathrm{a}(1,1)$ is projected on point ( $\mathrm{x} 0, \mathrm{y} 0+$ height), $\mathrm{a}(1, \mathrm{n})$ on ( $\mathrm{x} 0+$ width,y0+height), $\mathrm{a}(\mathrm{m}, 1)$ on ( $\mathrm{x} 0, \mathrm{y} 0$ ), and $\mathrm{a}(\mathrm{m}, \mathrm{n})$ on (x0+width,y0). Options: line_type, line_width, key, wired_surface, enhanced3d and color (see table F.5.1 on page 269 for color-names).
- explicit
- implicit
- label
- mesh (row_1,row_2,...) - Argument row_i is a list of n 3D points of the form [[x_i1,y_i1,z_i1], ...,[x_in,y_in,z_in]], and all rows are of equal length. All these points define an arbitrary surface in 3D. It's a generalization of the elevation_grid object. Options: line_type, line_width, color, key, wired_surface, enhanced3d and transform (see table F.5.1 on page 269 for color-names).
- parametric
- parametric_surface
- points
- quadrilateral
- spherical
- triangle
- tube (xfun,yfun,zfun,rfun,p,pmin,pmax). Draws a tube in 3D. (xfun,yfun,zfun,rfun) is the parametric curve with parameter $p$ taking values from pmin to pmax. Circles of radius $r f u n(p)$ are placed with their centers on the parametric curve and

Figure F.5.7. The trefoil knot
perpendicular to it. Options: xu_grid, yv_grid, line_type, line_width, key, wired_surface, enhanced3d, color and capping (see table F.5.1 on the next page for color-names). The command

```
draw3d(
    enhanced3d = true,
    xu_grid =100,
    tube((3+\operatorname{cos}(3*t))*\operatorname{cos}(2*t),
        (3+\operatorname{cos}(3*t))*\operatorname{sin}(2*t),
        sin (3*t) ,.5,t,-%pi,%pi)
);
```

produces the image of an overhand knot in figure F.5.7.

- vector ( $[\mathrm{x}, \mathrm{y}, \mathrm{z}],[\mathrm{dx}, \mathrm{dy}, \mathrm{dz}]$ ) - Draws the vector [dx,dy,dz] starting from $[x, y, z]$. Options: head_both, head_length, head_angle, head_type, line_width, line_type, key and color (see table F.5.1 on the next page for color-names).
The options explicit or implicit are required if functions are plotted. plot2d automatically decided whether a plot is explicit or implicit by how one codes it. The draw-library requires you to specify.
Within a scene, plots of functions (not all plots are of functions!) are either
$\triangleright$ explicit - plots of functions that you list, or
$\triangleright$ implicit - plots defined by equations.
As the examples in figures F.5.4 and F.5.5 on page 265 show, it is usually better to draw one scene at a time. The following abbreviations make this easier:
draw2d(stuff)=draw(gr2d(stuff)) Its options (including global ones) are identical to those of gr2d.
$\triangleright \operatorname{draw3d}($ stuff $)=\operatorname{draw}(\operatorname{gr3d}($ stuff $))$ Its options (including global ones) are identical to those of gr2d.
Example:

| white | black | gray0 | grey0 |
| :---: | :---: | :---: | :---: |
| gray10 | grey10 | gray20 | grey20 |
| gray30 | grey30 | gray40 | grey40 |
| gray50 | grey50 | gray60 | grey60 |
| gray70 | grey70 | gray80 | grey80 |
| gray90 | grey90 | gray100 | grey100 |
| gray | grey | light_gray | light_grey |
| dark_gray | dark_grey | red | light_red |
| dark_red | yellow | light_yellow | dark_yellow |
| green | light_green | dark_green | spring_green |
| forest_green | sea_green | blue | light_blue |
| royalblue | skyblue | cyan | light_cyan |
| dark_cyan | magenta | light_magenta | dark_magenta |
| turquoise | light_turquoise | dark_turquoise | pink |
| light_pink | dark_pink | coral | light_coral |
| orange_red | salmon | light_salmon | dark_salmon |
| aquamarine | khaki | dark_khaki | goldenrod |
| light_goldenrod | dark_goldenrod | gold | beige |
| brown | orange | dark_orange | violet |
| dark_violet | plum | purple | "xhhhhhhh" |

TABLE F.5.1. Colors in the draw-library

## Solutions to Selected Exercises

Chapter 1, 1.1 Exercise 1 (p. 7) The number of 5-card sets one can form from a 52card deck is binomial( 52,5 ), which is 2598960.
Chapter 1, 1.1 Exercise 2 (p. 7) The command rectform( $2 /(3+\% \mathrm{i})$ ); gives

$$
\frac{3}{5}-\frac{i}{5}
$$

Chapter 1, 1.1 Exercise 3 (p. 7) The command rectform $(3 * \% i+1 /(1-\% i))$; gives

$$
\frac{1}{2}+\frac{7 i}{2}
$$

Chapter 1, 1.1 Exercise 4 (p. 7) According to the Binomial Theorem

$$
\begin{aligned}
& \cos n \theta+i \sin n \theta=(\cos \theta+i \sin \theta)^{n} \\
& \quad=\cos ^{n} \theta+n \cos ^{n-1} \theta \cdot i \sin \theta+\frac{n(n-1)}{2!} \cos ^{n-2} \theta \cdot i^{2} \sin ^{2} \theta+\cdots \\
& \quad+n \cos \theta \cdot i^{n-1} \sin ^{n-1} \theta+i^{n} \sin ^{n} \theta
\end{aligned}
$$

so the real part of this equation gives

$$
\cos n \theta=\cos ^{n} \theta-\frac{n(n-1)}{2!} \cos ^{n-2} \theta \sin ^{2} \theta+\frac{n(n-1)(n-2)(n-3)}{4!} \cos ^{n-4} \theta \sin ^{4} \theta+\cdots
$$

and the imaginary part gives

$$
\sin n \theta=n \cos ^{n-1} \theta \sin \theta-\frac{n(n-1)(n-2)}{3!} \cos ^{n-3} \theta \sin ^{3} \theta+\cdots
$$

Chapter 2, 2.1 Exercise 1 (p. 14) Proposition 2.1.6 on page 12 shows that $\operatorname{gcd}(n, m)=1$ if and only if $n$ and $m$ have no primes in common in their prime-power factorizations.
Chapter 2, 2.1 Exercise 2 (p. 14) Define a function $f: \mathbb{Z}_{n \cdot m}^{\times} \rightarrow \mathbb{Z}_{n}^{\times} \times \mathbb{Z}_{m}^{\times}$by mapping $x \in \mathbb{Z}_{n \cdot m}^{\times}$to $(x \bmod n, x \bmod m) \in \mathbb{Z}_{n}^{\times} \times \mathbb{Z}_{m}^{\times}$. The Chinese Remainder Theorem implies that this is 1-1.
Chapter 2, 2.2 Exercise 1 (p. 15) Because $\phi(100)=40$ (use the totient-command), and $40 \mid 1000$, so $7^{1000} \equiv 1(\bmod 100)$.
Chapter 3, 3.0 Exercise 1 (p. 28) If we set r:allroots( $x^{\wedge} 5+2^{*} x-5$ ); we get equations 3.0.2 on page 28. Now do
$\operatorname{map}(\mathbf{r h s}$, r) or map('rhs,r) and you will get
[1.208917813386895,
$0.9409544200647337 * \% \mathrm{i}-1.167042002184508$,
$-0.9409544200647337 * \% \mathrm{i}-1.167042002184508$,
$1.234436184384533 * \% \mathrm{i}+0.5625830954910601$,
$0.5625830954910601-1.234436184384533 * \%$ i]
with no $\mathrm{x}=$.

Chapter 3, 3.3 Exercise 1 (p. 39) The implicit equation is

$$
x^{2}+2 y x^{2}+2 y^{2} x^{2}+y x-y^{2} x-y=0
$$

Chapter 3, 3.3 Exercise 2 (p. 39) The resultant is

$$
r=4 y^{2} x^{2}-x^{2}+y^{2}
$$

so the implicit equation is $r=0$.
Chapter 3, 3.3 Exercise 3 (p. 39) The implicit equation is

$$
-2 y+1-2 x-2 y x^{2}+x^{2}=0
$$

Chapter 3, 3.3 Exercise 4 (p. 39) The resultant in question is

$$
x^{4}+2 x^{3}+x^{2}-4 x=x(x-1)\left(x^{2}+3 x+4\right)
$$

It follows that $x$ can have one of the 4 values

$$
\left\{0,1, \frac{-3 \pm i \sqrt{7}}{2}\right\}
$$

Each of these $x$-values turns out to correspond to a unique $y$-value. Our four solutions are

$$
(x, y)=\left\{(0,1),(1,0),\left(\frac{-3-i \sqrt{7}}{2}, \frac{3-i \sqrt{7}}{2}\right),\left(\frac{-3+i \sqrt{7}}{2}, \frac{3+i \sqrt{7}}{2}\right)\right\}
$$

The solve-command will also reach this solution.
Chapter 3, 3.3 Exercise 5 (p. 39) We get

$$
\begin{aligned}
\operatorname{Res}\left(s+t-x, s^{2}-t^{2}-y, s\right) & =-2 x t+x^{2}-y \\
\operatorname{Res}\left(s^{2}-t^{2}-y, 2 s-3 t^{2}-z, s\right) & =9 t^{4}+6 t^{2} z-4 t^{2}-4 y+z^{2} \\
\operatorname{Res}\left(s+t-x, 2 s-3 t^{2}-z, s\right) & =-3 t^{2}-2 t+2 x-z
\end{aligned}
$$

and

$$
\begin{aligned}
& R=\operatorname{Res}\left(-2 x t+x^{2}-y,-3 t^{2}-2 t+2 x-z, t\right)= \\
& \quad-3 x^{4}+4 x^{3}+6 x^{2} y-4 x^{2} z+4 y x-3 y^{2}
\end{aligned}
$$

so the implicit equation is

$$
3 x^{4}-4 x^{3}-6 x^{2} y+4 x^{2} z-4 y x+3 y^{2}=0
$$

If we compute the resultant of $9 t^{4}+6 t^{2} z-4 t^{2}-4 y+z^{2}$ and $-2 x t+x^{2}-y$ we get

$$
\begin{aligned}
& 9 x^{8}-36 x^{6} y+24 x^{6} z-16 x^{6}+54 x^{4} y^{2} \\
& \quad-48 x^{4} y z-32 x^{4} y+16 x^{4} z^{2} \\
& \quad-36 x^{2} y^{3}+24 x^{2} y^{2} z-16 x^{2} y^{2}+9 y^{4}
\end{aligned}
$$

which turns out to be a multiple of $R$.
Chapter 4, 4.1 Exercise 1 (p. 49) Use the command

```
desolve(['diff(x(t),t)=3*x(t)-4*y(t),
'diff(y(t),t)=2*x(t)+3*y(t)],[x(t),y(t)]);
```

Figure F.5.8. Output of exercise plot
to get

$$
\begin{aligned}
& x(t)=-\frac{2 y(0) \% e^{3 t} \sin \left(2^{\frac{3}{2}} t\right)-\sqrt{2} x(0) \% e^{3 t} \cos \left(2^{\frac{3}{2}} t\right)}{\sqrt{2}} \\
& y(t)=\frac{x(0) \% e^{3 t} \sin \left(2^{\frac{3}{2}} t\right)+\sqrt{2} y(0) \% e^{3 t} \cos \left(2^{\frac{3}{2}} t\right)}{\sqrt{2}}
\end{aligned}
$$

Chapter 4, 4.1 Exercise 2 (p. 49) Write

$$
\begin{aligned}
\frac{d y}{d x} & =\text { yprime } \\
\frac{d \text { yprime }}{d x} & =3 * \text { yprime }^{3}-2 * y
\end{aligned}
$$

Chapter 4, 4.1 Exercise 3 (p. 49) First, notice that the ode2-command gives False, admitting defeat in solving this differential equation exactly. We solve the exercise by typing:

```
plotdf(x-y^2,[xfun," sqrt(x);-sqrt(x)"],
[trajectory_at, -1,3],
[direction, forward],
[y,-5,5], [x,-4,16]);
```

It's interesting to note that the solution-curve approaches $\sqrt{x}$ in the limit as $x \rightarrow \infty$.
Clicking on other points on the plot shows that this is almost always the case.
Chapter 4, 4.1 Exercise 4 (p. 49)

```
plotdf([v,-k*z/m], [z,v],
[parameters,"m=2,k=2"],
[sliders,"m=1:5"],
[trajectory_at, 6,0])
```

To produce figure F.5.8.
If we run this with [versus_t, $\mathbf{t}$ ], we also get plots of z and v .
Chapter 4, 4.1 Exercise 5 (p. 49) Try expand(\%) and ratsimp a second time.

Chapter 4, 4.2 Exercise 1 (p. 52) If $\mathbf{v}$ is the velocity-vector, we have

$$
\mathbf{v}=\left[\begin{array}{l}
v_{h} \\
v_{v}
\end{array}\right]
$$

its vertical and horizontal components. We have equations

$$
\begin{align*}
& m \frac{d v_{v}}{d t}=-9.8 m \\
& m \frac{d v_{h}}{d t}=0 \tag{F.5.1}
\end{align*}
$$

where $m$ is the mass of the cannonball. At time zero $v_{v}=1000 \sin 30^{\circ}=500 \mathrm{~m} / \mathrm{sec}$, and $v_{h}=1000 \cos 30^{\circ}=866.025$. We get

$$
\begin{aligned}
v_{v} & =500-9.8 t \\
y & =500 t-4.9 t^{2}
\end{aligned}
$$

The apogee occurs when $v_{v}=0$ or at time $500 / 9.8$. This gives a value of $y$ equal to 12755.10204081632.

Chapter 4, 4.2 Exercise 2 (p. 52) If $\mathbf{r}$ is the vector representing the air-resistance, we must have $\mathbf{r}=-\alpha \mathbf{v}$, where $\mathbf{v}$ is the velocity vector of the cannonball and $\alpha>0$ is a scalar. The constant in equation 4.2.1 on page 52 is $\frac{1}{2} C_{D} \rho A=.057575$ and we have $|\mathbf{r}|=.057575|\mathbf{v}|^{2}$ so

$$
\mathbf{r}=-.057575|\mathbf{v}| \mathbf{v}
$$

Our equations of motion (equation F.5.1) become

$$
\begin{align*}
& m \frac{d v_{v}}{d t}=-9.8 m-.057575 v_{v} \sqrt{v_{h}^{2}+v_{v}^{2}} \\
& m \frac{d v_{h}}{d t}=-.057575 v_{h} \sqrt{v_{h}^{2}+v_{v}^{2}} \tag{F.5.2}
\end{align*}
$$

where the mass is very significant now ${ }^{3}$. Dividing by the mass of 4 kg gives

$$
\begin{align*}
& \frac{d v_{v}}{d t}=-9.8-0.01439375 v_{v} \sqrt{v_{h}^{2}+v_{v}^{2}} \\
& \frac{d v_{h}}{d t}=-0.01439375 v_{h} \sqrt{v_{h}^{2}+v_{v}^{2}}  \tag{F.5.3}\\
& \frac{d x}{d t}=v_{h}  \tag{F.5.4}\\
& \frac{d y}{d t}=v_{v} \tag{F.5.5}
\end{align*}
$$

The first two equations are highly nonlinear, so we must use $\mathbf{r k}$ to solve them.

```
cannon:rk([-9.8-0.01439375*vv*sqrt(vv^2+vh^2),
-0.01439375*vh*sqrt(vv^2+vh^2),vv,vh],[vv,vh,y,x],
[500,866.025,0,0],[t,0,10,.01]);
```

Examining the output show that the apogee occurs at time 2.64 seconds and that $y$ (the altitude) is 110.389 meters. We can reformat the output-list to graph the cannonball's progress:

```
height:makelist([ elt[1], elt[4]],elt,cannon)
plot2d([discrete,height],[y,0,200])
```

We get

[^47]

Chapter 4, 4.6 Exercise 2 (p. 73) Since $x$ and $y$ are independent variables

$$
\begin{aligned}
& \int_{-\pi}^{\pi} \int_{\pi}^{\pi} \sin (n x) \sin (m y) \cdot \sin (\bar{n} x) \sin (\bar{m} y) d x d y \\
&=\left(\int_{-\pi}^{\pi} \sin (n x) \sin (\bar{n} x) d x\right)\left(\int_{-\pi}^{\pi} \sin (m y) \sin (\bar{m} y) d y\right)
\end{aligned}
$$

so the conclusion follows from equation 4.3 .5 on page 54 . This is why two-dimensional Fourier series work; indeed it is why $n$-dimensional Fourier series work.
Chapter 5, 5.2 Exercise 1 (p. 80) We could just use definition 5.2 .1 on page 78 and straight computation (ugh!). Or we could use equation 5.2.4 on page 79 and the fact that multiplication is commutative and associative.
Chapter 5, 5.2 Exercise 2 (p. 80) Because the Fast Fourier Transform algorithm requires the length of the sequences to be a power of 2 .
Chapter 5, 5.2 Exercise 4 (p. 80) Since the result will be of degree 9 , the sequence of coefficients will be of length 10 . The next higher power of 2 is $2^{4}=16$. Let

```
load ("fft");
fpprintprec : 4; /* number of digits to print */
A : [2 , -4,1, -1,0,0,0,0,0,0,0,0,0,0,0,0];
ia:inverse_fft(A);
ia3:ia^3; /* element by element operation */
A3:realpart(fftt(ia3));
[8.0,-48.0,108.0,-124.0,102.0,-72.0,31.0,-15.0,3.0,-1.0,
-2.132*1\mp@subsup{0}{}{\wedge}-14,2.842*1\mp@subsup{0}{}{\wedge}-14,-2.132*10^-14,
1.421*10^ - 14,0, -3.553*10^ - 15]
```

The terms after the 10th are due to round-off errors. The result is

$$
8-48 x+108 x^{2}-124 x^{3}+102 x^{4}-72 x^{5}+31 x^{6}-15 x^{7}+3 x^{8}-x^{9}
$$

which you can verify by (tedious!) direct computation.
Chapter 7, 7.1 Exercise 2 (p. 107) In Manifold Theory and Differential Geometry (see [3]), volumes have an orientation. In $\mathbb{R}^{n}$ the standard orientation is

$$
\left\{x_{1}, \ldots, x_{n}\right\}
$$

and if you swap any pair of axes, the result has a negative orientation.
Chapter 7, 7.2 Exercise 3 (p. 109) Just form the matrix

$$
P=\left[\begin{array}{ccc}
8 & -1 & 2 \\
4 & 0 & 1 \\
3 & -1 & 1
\end{array}\right]
$$

and compute

$$
\left(P^{-1}\right) \cdot A \cdot P=\left[\begin{array}{ccc}
-27 & 5 & -8 \\
53 & -10 & 15 \\
137 & -25 & 40
\end{array}\right]
$$

Chapter 7, 7.4 Exercise 1 (p. 120)
(F.5.6) $\quad A^{n}=\left[\begin{array}{ccc}-2^{n+2}-3^{n+1}+8 & 3^{n}-1 & -3^{n}-2^{n}+2 \\ 2^{n+3}-8 & 1 & 2^{n+1}-2 \\ 5 \cdot 2^{n+2}+4 \cdot 3^{n+1}-32 & 4-4 \cdot 3^{n} & 4 \cdot 3^{n}+5 \cdot 2^{n}-8\end{array}\right]$

Chapter 7, 7.4 Exercise 2 (p. 120) Just plug $n=1 / 2$ into equation F.5.6 to get

$$
\sqrt{A}=\left[\begin{array}{ccc}
-4 \sqrt{2}-3 \sqrt{3}+8 & \sqrt{3}-1 & -\sqrt{3}-\sqrt{2}+2 \\
8 \sqrt{2}-8 & 1 & 2 \sqrt{2}-2 \\
20 \sqrt{2}+12 \sqrt{3}-32 & 4-4 \sqrt{3} & 4 \cdot \sqrt{3}+5 \sqrt{2}-8
\end{array}\right]
$$

Chapter 7, 7.5 Exercise 2 (p. 131) We know

$$
\begin{aligned}
x^{\left[\begin{array}{ll}
1 & 2 \\
3 & 4
\end{array}\right]} & =e^{\left(\log (x) \cdot\left[\begin{array}{ll}
1 & 2 \\
3 & 4
\end{array}\right]\right)} \\
& =e^{\left[\begin{array}{cc}
\log (x) & 2 \log (x) \\
3 \log (x) & 4 \log (x)
\end{array}\right]}
\end{aligned}
$$

We type

```
z:matrix ([log(x),2*\operatorname{log}(x)],[3*\operatorname{log}(x),4*\operatorname{log}(x)]);
a:matrixexp(z);
```

and get a very messy and convoluted expression that none of our normal simplification commands improve until we type
radcan (a);
which gives

$$
\left[\begin{array}{cc}
-\frac{(\sqrt{3} \sqrt{11}-11) x^{\sqrt{3} \sqrt{11}+2}+(-\sqrt{3} \sqrt{11}-11) x^{2}}{222^{\frac{\sqrt{3} \sqrt{11}-1}{2}}} & \frac{2 \sqrt{3} \sqrt{11} x^{\sqrt{3} \sqrt{11}+2}-2 \sqrt{3} \sqrt{11} x^{2}}{333} \\
\frac{\sqrt{3} \sqrt{11} x^{\sqrt{3} \sqrt{11}+2}-\sqrt{3} \sqrt{11} x^{2}}{11 x^{\frac{\sqrt{3} \sqrt{11}-1}{2}}} & \frac{(\sqrt{3} \sqrt{11}+11) x^{\frac{\sqrt{3}}{11}+2}+(11-\sqrt{3} \sqrt{11}) x^{2}}{22 x^{\frac{\sqrt{3} \sqrt{11}-1}{2}}}
\end{array}\right]
$$

We can further simplify this by hand.
Chapter 7, 7.6 Exercise 1 (p. 135) We begin with $j=$ number of jackets and $p=$ number of pants. The objective function is

$$
3 p+2 j
$$

Our constraints are

$$
8 p+4 j \leq 60
$$

and

$$
4 p+8 j \leq 48
$$

So we formulate this as

```
maximize_lp ( }3*\textrm{p}+2*\textrm{j},\quad[8*\textrm{p}+4*\textrm{j}<=60,4*\textrm{p}+8*\textrm{j}<=48]
```

and Maxima comes back with

$$
[24,[p=6, j=3]]
$$

Chapter 7, 7.6 Exercise 2 (p. 136) It's a good idea to restart Maxima (using that command on the Maxima menu) and reload the simplex library. We set
$\mathrm{p}=$ potatoes, $\mathrm{c}=$ corn. The profit (objective function) is

$$
150 p+50 c
$$

and the constraints are

$$
\begin{aligned}
20 p+60 c & \leq 3000 \\
p+c & \leq 70
\end{aligned}
$$

As before, we write
$\boldsymbol{\operatorname { m a x i m i z e }} \_\mathbf{l} \mathbf{p}(150 * \mathrm{p}+50 * \mathrm{c}, \quad[20 * \mathrm{p}+60 * \mathrm{c}<=3000, \mathrm{p}+\mathrm{c}<=70])$
and get
Problem not bounded!
Potatoes are so profitable, it's worthwhile to grow "negative" corn to increase the production of potatoes. We must insist that negative potatoes and corn do not exist!

$$
\operatorname{maximize} \_l p(150 * p+50 * c, \quad[20 * p+60 * c<=3000, p+c<=70, p>=0, c>=0])
$$

and get

$$
[10500,[p=70, c=0]]
$$

so there's no point in planting any corn!
Chapter 8, 8.1 Exercise 1 (p. 147) Equation 8.1.1 on page 144 implies that

$$
\Sigma x_{(-i)}=\mathbf{E} \frac{x_{(1-i)}}{1-i}
$$

In the case where $i=1$, we get

$$
\Sigma_{0}^{n} x_{(-1)}=1+\frac{1}{2}+\cdots+\frac{1}{n+1}=H_{n+1}
$$

the $n+1$ st Harmonic number. This shows that the harmonic numbers play a part in finite-difference calculus similar to that of the logarithm in regular calculus.
Chapter 8, 8.1 Exercise 2 (p. 147) There's nothing to prove if $n=0,1$. Assume it has been proved for all values of $n<k$, and we want to proved it for $x^{k}$. The lowestdegree falling factorial that contains a term of $x^{k}$ is $x_{(k)}$, and it contains a single term of $x^{k}$. It follows that

$$
x^{k}-x_{(k)}
$$

consists of a linear combination of powers $x^{i}$ with $i<k$. By the induction hypothesis

$$
x^{k}-x_{(k)}=\sum_{i=0}^{k-1} a_{i} x_{(i)}
$$

with $a_{i} \in \mathbb{Z}$, and

$$
x^{k}=x_{(k)}+\sum_{i=0}^{k-1} a_{i} x_{(i)}
$$

Chapter 8, 8.1 Exercise 3 (p. 147) Straight (somewhat tedious) computation.
Chapter 8, 8.1 Exercise 5 (p. 147) Since the equation is linear, proving it for some class of functions proves it for all possible linear combinations of these functions. It's sufficient to prove for $f(x)=x^{n}$ for all integers $n \geq 0$. Since these functions are linear combinations of falling factorials (exercise 2 on page 147), it suffices to prove
it for all falling factorials $x_{(n)}$ with $n$ an integer $\geq 0$. If we set $a=0$ in equation 8.1.4 on page 144 , we get

$$
S=0+\Delta\left[x_{(n)}\right](0)(x)_{(1)}+\frac{\Delta^{2}\left[x_{(n)}\right](0)(x)_{(2)}}{2!}+\frac{\Delta^{3}\left[x_{(n)}\right](0)(x)_{(3)}}{3!}+\cdots
$$

Now

$$
\Delta^{i}\left[x_{(n)}\right](0)(x)_{(i)}=n(n-1) \cdots(n-i+1) x_{(n-i)}(0)= \begin{cases}0 & \text { if } i<n \\ n! & \text { if } i=n \\ 0 & \text { if } i>n\end{cases}
$$

so $S=x_{(n)}$.
Chapter 8, 8.1 Exercise 6 (p. 147) Just write $\boldsymbol{\Delta}=\mathrm{E}-1$ and plug it in:

$$
\begin{aligned}
(\mathbf{E}-1)(f g) & =\mathbf{E}(f) \mathbf{E}(g)-f g \\
& =(\mathbf{E}(f)-f) \mathbf{E}(g)+f \mathbf{E}(g)-f g \\
& =(\mathbf{E}(f)-f) \mathbf{E}(g)+f \cdot(\mathbf{E} g-g) \\
& =\Delta f \mathbf{E}(g)+f \Delta g
\end{aligned}
$$

Chapter 8, 8.1 Exercise 7 (p. 147) Just plug equation 8.1 .7 on page 147 into $\Sigma_{a}^{b}$ and rearrange terms.
Chapter 8, 8.1 Exercise 8 (p. 148) Yes. Consider the vector-space spanned by $\left\{x^{n}\right\}$ for $n$ an integer $\geq 0$. In this vector-space, the operators $\mathbf{E}, \boldsymbol{\Delta}$, and $\mathbf{D}$ are (infinite) matrices and equation 8.1.6 on page 145 is literally true.
Chapter 8, 8.1 Exercise 9 (p. 148) Set $f(x)=x$ and $g(x)=2^{x}$. Then $\Delta g=g, \Delta f=1$, and we get

$$
\begin{aligned}
\boldsymbol{\Sigma}_{0}^{n} f \Delta g & =\mathbf{E}(f g)(n)-(f g)(0)-\boldsymbol{\Sigma}_{0}^{n} \mathbf{E}(g) \Delta f \\
& =(n+1) 2^{n+1}-\sum_{k=0}^{n} 2^{k+1^{\prime}} \\
& =(n+1) 2^{n+1}-2 \sum_{k=0}^{n} 2^{k} \\
& =(n+1) 2^{n+1}-2\left(2^{n+1}-1\right) \\
& =(n+1) 2^{n+1}-2^{n+2}+2
\end{aligned}
$$

Chapter 8, 8.1 Exercise 10 (p. 148) This is easier than it looks. Code
$\left.z(n):=\operatorname{ratsimp}\left(1-t^{\wedge} n\right) /(1-t)\right)$
Then
z (3)
produces

$$
t^{2}+t+1
$$

It's not hard to see that for $n>0$ an integer,

$$
\frac{1-t^{n}}{1-t}=1+t+\cdots+t^{n-1}
$$

Integrating this gives the conclusion.
Chapter 8, 8.2 Exercise 4 (p. 152) You can just write

```
Bdeltan(f,x,m) := buildq([y:x, g:f, n:m],
    lambda([y],
    sum((-1)^(k+1)*\boldsymbol{binomial}(\textrm{n},\textrm{k})*g(y+k),
        k,0,n))
    );
```

or (more efficiently)

```
Bdeltan(f,x,m) := buildq([y:x, g:f, n:m],
    lambda([y],
    -sum((-1)^k*\operatorname{binomial}(n,k)*g(y+k),
        k,0,n))
    );
```

Chapter 9, 9.5 Exercise 1 (p. 161) Typing

```
poly_reduced_grobner([ [ < 2 2+y^2, x^3-y^4],[x,y])
```

returns

$$
\left[y^{2}+x^{2}, y^{4}+x y^{2}, y^{6}+y^{4}\right]
$$

so the original equations are equivalent to

$$
\begin{aligned}
y^{2}+x^{2} & =0 \\
y^{4}+x y^{2} & =0 \\
y^{6}+y^{4} & =0
\end{aligned}
$$

The last equation implies that $y=0, \pm i$. The first equation implies that, if $y=0$, then $x=0$. The second equation implies that, if $y= \pm i$, then $x=1$. So the solutions to the original equations are

$$
\begin{aligned}
& x=y=0, \\
& x=1, y= \pm i
\end{aligned}
$$

So there are a total of three solutions.
Chapter 9, 9.5 Exercise 2 (p. 161) Define an ideal and type

```
poly_reduced_grobner([ a 1 *a2-b1*b2+a1-1,
a2*b1+a1*b2+b1-1/2,a1^2+b1^2-1,a2^2+b2^2-1],[a1, b1, a2 ,b2])
```

to get

$$
\left[64 \mathrm{~b} 2^{2}-55,-4 \mathrm{~b} 2+10 \mathrm{a} 1-5,-16 \mathrm{~b} 2-20 \mathrm{~b} 1+5,8 \mathrm{a} 2+3\right]
$$

from which we deduce that $a_{2}=-3 / 8$ and $b_{2}$ can be either $+\sqrt{55} / 8$ in which case

$$
\begin{aligned}
& a_{1}=1 / 2+\sqrt{55} / 20 \\
& b_{1}=1 / 4-\sqrt{55} / 10
\end{aligned}
$$

or $-\sqrt{55} / 8$ in which case

$$
\begin{aligned}
& a_{1}=1 / 2-\sqrt{55} / 20 \\
& b_{1}=1 / 4+\sqrt{55} / 10
\end{aligned}
$$

The solve-command also works in this case.

Chapter 9, 9.5 Exercise 3 (p. 161) Make this into an ideal problem:
Create an ideal

$$
\left(\left(a^{2}+1\right)\left(b^{2}+1\right)+25-10(a+b), a b-1, a^{3}+b^{3}-z\right)
$$

and find a Gröbner basis with $a \succ b \succ z$ :
Typing

```
poly_reduced_grobner \(\left(\left[\left(a^{\wedge} 2+1\right) *\left(b^{\wedge} 2+1\right)+25-10 *(a+b)\right.\right.\),
\(\left.\left.a^{\wedge} 3+b^{\wedge} 3-z, a * b-1\right],[a, b, z]\right)\);
```

gives

$$
\left[-b z+72 b^{2}-250 b+72,-z^{2}+220 z-12100,-z+72 b+72 a-250\right]
$$

and
solve $\left(-z^{\wedge} 2+220 * z-12100=0, z\right)$;
gives $z=110$.
Chapter 9, 9.5 Exercise 4 (p. 161) Type

```
poly_reduced_grobner ([ [ < ^2+ }x*y+y^\mp@subsup{y}{}{\wedge}2-39
y^2+y*z+z^}2-49,\mp@subsup{z}{}{\wedge}2+z*x+x^2-19],[x,y,z])
```

to get

$$
\left[-7 z^{3}+58 z+3 y,-7 z^{4}+64 z^{2}-9,7 z^{3}-67 z+6 x\right]
$$

and type
solve ( $\left.-7 * z^{\wedge} 4+64 * z^{\wedge} 2-9, z\right)$;
to get

$$
\left[z=-\frac{1}{\sqrt{7}}, z=\frac{1}{\sqrt{7}}, z=-3, z=3\right]
$$

Now you can solve for the $x$ and $y$ values that go with these $z$-values:
$\triangleright$ If $z=-1 / \sqrt{7}$, then $y=19 / \sqrt{7}, x=-11 / \sqrt{7}$.
$\triangleright$ If $z=1 / \sqrt{7}$, then $y=-19 / \sqrt{7}, x=11 / \sqrt{7}$.
$\triangleright$ If $z=3$, then $y=5, x=2$.
$\triangleright$ If $z=-3$, then $y=-5, x=-2$.
Chapter 9, 9.5 Exercise 5 (p. 162) Type

```
poly_reduced_grobner ([a1*x1^5 + a 2*x2^5 + a 3*x3^5 - 1/6,
a1*x1^4 + a2*x2^4 + a3*x3^4 - 1/5,
a1*x1^3 + a2*x2^3 + a3*x3^3 - 1/4,
a1*x1^2 + a2*x2^2 + a3*x3^2 - 1/3,
a1*x1 + a2*x2 + a3*x3 - 1/2,
a1 + a2 + a3 - 1],
[x1,x2,x3,a1,a2,a3]);
```

to get a basis that contains the term

$$
162 \cdot a 2^{2}-117 \cdot a 2+20
$$

The command

```
solve(162*a2^2-117*a2 +20=0,a2);
```

produces

$$
\left[\mathrm{a} 2=\frac{5}{18}, \mathrm{a} 2=\frac{4}{9}\right]
$$

Adding a2-4/9 to the original list produces a Gröbner basis of

$$
\left[9 \cdot a 2-4,5-18 \cdot a 3,1-2 \cdot x 2,5-18 \cdot a 1,-x 3-x 1+1,-10 \cdot x 3^{2}+10 \cdot x 3-1\right]
$$

From which it is straightforward to get all the other values.
Chapter 10, 10.2 Exercise 1 (p. 172) Run the Maxima command

```
poly_reduced_grobner ([ a 5 * a 4 *a3-a5 * b 4*b3+a5*a4-x,
b5*a4*a3-b5*b4*b3+b5*a4-y,
b4*a3+a4*b3+b4-z,
x^2+y^2+z^2-r^2,
a2^2+b2^2-1,
a3^2+b3^2-1,
a4^2+b4^2-1,
a5^2+b5^2-1],
[a5,a4,a3,a2,b5,b4,b3,b2,x,y,z,r]);
```

and, in the long list of expressions in the Gröbner basis there is

$$
-r^{4}+4 * r^{2}-4 * b 3^{2}
$$

Since $b 3^{2} \geq 0$, we must have $-r^{4}+4 r^{2} \geq 0$ or $r \leq 2$. We could have come to the same conclusion by the fact that the robot-arm has two links of length 1 !
Chapter 12, 12.1 Exercise 1 (p. 191) We get

$$
(x)_{m}=\frac{\Gamma(x+1)}{\Gamma(x-m+1)}
$$

If $x$ and $m$ are integers and $m>x$, then the denominator is $\Gamma$ evaluated at 0 or a negative integer, which is infinite, so the quotient will be 0 .
Chapter 12, 12.1 Exercise 2 (p. 191) Unfortunately, the gamma command just crashes if it's fed an argument that is a nonpositive integer (i.e., it doesn't return inf). We must first check that case and return 0 . We get

```
ff (x,m) := block(
    [a:imagpart(x-m+1),b:realpart(x-m+1)],
    if(a = 0 and (b <=0 ) and #Test for
                                    #a negative
                                    #real integer
        abs (mod}(\textrm{b},1))<.000001
    then return (0),
        gamma(x+1)/gamma(x-m+1)
    );
```

If $x$ and $m$ are integers and $m>x$, then the denominator is $\Gamma$ evaluated at 0 or a negative integer, which is infinite, so the quotient will be 0 .
Chapter 12, 12.1 Exercise 3 (p. 192) Use the $\Gamma$-function! Our formula in the exercise becomes

$$
\frac{d^{k} x^{n}}{d x^{k}}=\frac{\Gamma(n+1)}{\Gamma(n-k+1)} x^{n-k}
$$

and

$$
\frac{d^{1 / 2} x}{d x^{1 / 2}}=\frac{x^{1 / 2}}{\sqrt{\pi} / 2}=\frac{2 x^{1 / 2}}{\sqrt{\pi}}
$$

Figure F.5.9. Plot of ellipse,same_xy

Chapter 12, 12.1 Exercise 4 (p. 192) Use the $\Gamma$-function! Our formula in the exercise becomes

$$
\frac{d^{1 / 2} x^{n}}{d x^{1 / 2}}=\frac{n!}{\Gamma(n+1 / 2)} x^{n-1 / 2}
$$

so

$$
\frac{d^{1 / 2} e^{x}}{d x^{1 / 2}}=\sum_{n=0}^{\infty} \frac{x^{n-1 / 2}}{\Gamma(n+1 / 2)}
$$

Although this function has a singularity at $x=0$, it actually converges to $e^{x}$ for larger values of $x$.
Chapter 12, 12.2 Exercise 1 (p. 197) Use the command
plot2d ([ parametric, jacobi_cd $(x, .9)$, jacobi_sd $(x, .9)$,
$[x, 0,10]]$, same_xy, [style ,[lines $, 2,5]]) ;$
to get the plot in figure F.5.9. If we leave out the 'same_xy' we get the well-proportioned but distorted plot in figure F.5.10 on the facing page.
Chapter 12, 12.2 Exercise 3 (p. 197) If the starting angle is $180^{\circ}$, the pendulum is vertical. This is an unstable equilibrium (very!), and the pendulum can theoretically remain in this position forever.
Chapter 12, 12.5 Exercise 2 (p. 207) Using Euler's formula

$$
e^{i x}=\cos x+i \sin x
$$

we get

$$
\mathrm{E}_{1}(i x)=i\left(-\frac{\pi}{2}+\mathrm{Si}(x)\right)-\mathrm{Ci}(x)
$$

Chapter 12, 12.6 Exercise 2 (p. 209) First, code a function

$$
\text { tow }(x):=-\operatorname{lambert} \_w(-\log (x)) / \log (x) \text {; }
$$

Basic experimentation shows that

$$
\text { float }(\text { sqrt }(2)+.030454298636671))
$$

Figure F.5.10. Plot without same_xy
is still real, and that its value is

$$
2.718281776395266
$$

which leads one to suspect that the maximum finite value of $t_{\infty}(x)$ is $e$. Note, this is not a local maximum, so taking the derivative of $t_{\infty}(x)$ and setting it to 0 will not work.

The value where this occurs is

$$
v=\sqrt{2}+.030454298636671=1.444667861009766
$$

If we randomly play around with this value, we eventually find

$$
\frac{1}{\log (v)}=2.718281828459046
$$

so

$$
v=e^{\frac{1}{e}}
$$

And, if we type

$$
\operatorname{tow}\left(\% \mathrm{e}^{\wedge}(1 / \% \mathrm{e})\right)
$$

we get

```
%e
```

as implied by equation 12.6 .4 on page 209 .
Chapter 12, 12.6 Exercise 3 (p. 210) Typing

```
x:tow (3)
```

gives

$$
-\frac{\text { lambert_w }(-\log (3))}{\log (3)}
$$

and

```
float(%)
```

gives

$$
-0.9102392266268373 \cdot(1.391335054072608 \cdot \% i-0.2524062904251475)
$$

The command

## rectform (\%)

gives

$$
y=0.2297501065923352-1.26644774359786 \cdot \% i
$$

What has happened here? Clearly the infinite power tower

$$
3^{3^{3^{3}}}
$$

isn't well-defined. The point is that we have solved the equation

$$
y=3^{y}
$$

which is still well-defined even when the power-tower is not. The solution, $y$, is a value with the property that

$$
y^{1 / y}=3
$$

If you type
$y^{\wedge}(1 / y)$
you get

$$
(0.2297501065923352-1.26644774359786 \cdot \% i)^{\frac{0.297501065923352-1.2664777435786 \cdot \% / i}{}}
$$

and

```
rectform(%)
```

gives

$$
6.661338147750939 \cdot 10^{-16} \cdot \% i+3.0
$$

where the imaginary part is round-off error.
Chapter 13, 13.2 Exercise 2 (p. 224) Since

$$
p(x)=\pi(x)+\pi\left(x^{1 / 2}\right) / 2+\pi\left(x^{1 / 3}\right) / 3+\cdots
$$

we get

$$
p(x)-p\left(x^{1 / 2}\right) / 2=\pi(x)+\pi\left(x^{1 / 3}\right) / 3+\pi\left(x^{1 / 5}\right) / 5 \cdots
$$

and

$$
\begin{aligned}
p(x)-p\left(x^{1 / 2}\right) / 2-p\left(x^{1 / 3}\right) / 3-p\left(x^{1 / 5}\right) / 5+p\left(x^{1 / 6}\right) / 6 & \\
& =\pi(x)+\pi\left(x^{1 / 7}\right) / 7+\cdots
\end{aligned}
$$

where, at each step the sum on the left consists of terms with the primes already covered and the sum on the right consists of none of those primes.
Chapter E, E. 5 Exercise 1 (p. 241) Write a function (look at equation 2.1.1 on page 10)
is_an_integer $(x):=$ is $(\bmod (x, 1)=0)$;
Actually, if $x$ is a real number involved in computations, it might be better to write is_an_integer $(x):=$ is $(\bmod (x, 1)<.0000001)$;

If $x$ can be a complex number, it might be better to write

```
is_an_integer(x):= is(abs(imagpart(x)) < .0000001)
    and is (mod(realpart (x),1) < .0000001);
```

[^0]:    ${ }^{1}$ FreeBSD, NetBSD, and OpenBSD.

[^1]:    ${ }^{2}$ Try typing bfloat(inf) and Cell $\triangleright$ Evaluate Cell(s) :

[^2]:    ${ }^{1}$ As a grad student at the Courant Institute, the author mentioned number theory and another student sneered "Does such a thing even exist?"

[^3]:    ${ }^{2}$ To the consternation of the CIA!

[^4]:    ${ }^{3}$ As it turns out!
    ${ }^{4}$ See appendix D on page 235.

[^5]:    ${ }^{5}$ So the computations are slightly faster.
    ${ }^{6}$ Acquired by some magic, perhaps!

[^6]:    ${ }^{7}$ Which may also be publicly-known.

[^7]:    ${ }^{1}$ The listed variable is regarded as the only variable; all others are treated as constants.
    ${ }^{2}$ We'll leave out the "hitting Cell $\triangleright$ Evaluate Cell(s) " from now on; it's implied.

[^8]:    3"quad" refers to quadrature, the act of estimating an area bounded by a curve (in ancient Greek, 'quad' literally refers to constructing a square of a given area). The author has no idea what 'qag' represents!

[^9]:    ${ }^{4}$ So the constants zeroa and zerob are unnecessary.

[^10]:    ${ }^{1}$ We can "absorb" the quotient by 2 into \%k1!
    ${ }^{2}$ Simplifying an expression is a complex process, and Maxima has several commands for doing this in different ways. It's not always clear what constitutes simplification.

[^11]:    ${ }^{3}$ In this simulation, you may see more atto-rabbits than foxes!

[^12]:    ${ }^{4}$ A function, $f(x)$, is called odd if $f(-x)=-f(x)$.

[^13]:    ${ }^{5}$ In other words, it is well-known but we won't prove it here. See [38].

[^14]:    ${ }^{6}$ Of course we could've preceded the ode 2 command with assume(lambda>0).
    ${ }^{7}$ We have absorbed the constant $\%$ c into $\% \mathrm{k} 1$ and $\% \mathrm{k} 2$.

[^15]:    ${ }^{8}$ The reader is invited to verify that this actually satisfies equation 4.6.1.

[^16]:    ${ }^{1}$ I.e., we're not going to prove this here!

[^17]:    ${ }^{2}$ This is easily derived from definition 6.2.1 on the preceding page, equations 4.3.3 on page $53,4.3 .6$ on page 54 , and 4.3 .7 on page 54 and a suitable $u$-substitution.

[^18]:    ${ }^{3}$ These are not obvious!

[^19]:    ${ }^{1}$ The use of a single carat, $\wedge$, is also well defined but it raises the entries in the matrix to powers, which is not correct.

[^20]:    ${ }^{2}$ They're both scalars!

[^21]:    ${ }^{3}$ It isn't necessary to issue the charpoly command or the eigenvalues command first.

[^22]:    ${ }^{4}$ It can't possibly be; the actual eigenvalue is irrational.

[^23]:    ${ }^{5}$ As anyone who has seen the old Star Trek episode, The Trouble with Tribbles, knows!

[^24]:    ${ }^{6}$ If $C$ and $C^{\prime}$ are any two distinct columns of the matrix, then $C \cdot C=1$ and $C \cdot C^{\prime}=0$.

[^25]:    ${ }^{7}$ This is the approximate value of Google when the company went public in 2004. This section of the book uses material from the excellent paper, [7].

[^26]:    ${ }^{8}$ Because it's trying to find exact values, solving degree-10 polynomials.

[^27]:    ${ }^{1}$ This is not at all obvious! Later, we will look at an algorithm for coming to this conclusion.

[^28]:    ${ }^{2}$ Also called dictionary-ordering.

[^29]:    ${ }^{3}$ The ones that will interest us, anyway.

[^30]:    ${ }^{1}$ In 1985, this type of robot-arm was used to do brain-surgery! See [26].

[^31]:    ${ }^{2}$ We could've concluded this from geometric reasoning: this is the length of a unit-vector manipulated by orthogonal transformations that leave length unchanged.

[^32]:    ${ }^{1}$ Stirred not shaken, of course!

[^33]:    ${ }^{2}$ Try running it!

[^34]:    ${ }^{3}$ Although finding 100-dimensional limos might be hard!

[^35]:    ${ }^{4}$ Reminiscent of an old road-sign in Ireland: "Don't drink while you drive; you might spill some."

[^36]:    ${ }^{1}$ This beautiful diagram was taken from Wikimedia, without attribution.

[^37]:    ${ }^{2}$ As its name implies.

[^38]:    ${ }^{3}$ Maxima documentation states that it's only defined for real values of $x>1$.

[^39]:    ${ }^{1}$ You can easily check this with Maxima!

[^40]:    ${ }^{2}$ Isn't it obvious?

[^41]:    ${ }^{3}$ For instance, type taylor $(\log (1-\mathrm{s}), \mathrm{s}, 0,20)$;

[^42]:    ${ }^{4}$ If we integrate it the other way, i.e. as the integral of $n^{\wedge}$ beta/beta, we get gamma_incomplete( $\left(0,-\right.$ beta* $\log (\mathrm{x})$ ), which equals $\operatorname{li}\left(x^{\beta}\right)$.

[^43]:    $5_{\text {It's counting powers of primes as well as primes themselves. }}^{\text {p }}$

[^44]:    ${ }^{6}$ I.e., an equation for primes!

[^45]:    ${ }^{1}$ Recursive definition!

[^46]:    ${ }^{1}$ They are predefined data-items.
    ${ }^{2}$ Generally a bad idea!

[^47]:    ${ }^{3}$ This is why a feather falls more slowly than a cannonball in the Earth's atmosphere.
